CONTENTS.

GENERAL SUMMARY OF THE MONOGRAPH.

| | Page. |
|------------------------------------------------------------------------------------------------------------------------------|-------|
| Acknowledgments..... | 11 |
| Bibliography..... | 13 |
| Synonymy, tabulated alphabetically by genera, subgenera, species, and varieties, with present references.... | 27 |
| Geographic and stratigraphic distribution, by species zoologically arranged..... | 98 |
| Geographic distribution, by continents, geologic provinces, and States or countries..... | 114 |
| Stratigraphic distribution by States or countries, with typical or general sections, correlating localities and fossils..... | 123 |
| Habitat, alphabetic list of genera and subgenera, giving data on..... | 160 |
| Localities, by number, with lists of fossils and reference to position in stratigraphic tables..... | 161 |
| Terminology adopted for the monograph..... | 291 |
| Definitions or glossary..... | 292 |
| The shell, structural features..... | 296 |
| Evolution, schematic diagram of, for all genera and subgenera..... | 317 |
| Classification, table and analysis..... | 321 |
| Description of genera and species..... | 327 |

CONTENTS IN DETAIL.

| | |
|--------------------------------------------------------------------------------------------------------------------|-----|
| Introduction..... | 11 |
| Preparation and scope..... | 11 |
| Acknowledgments..... | 11 |
| Historical data..... | 13 |
| Bibliography..... | 13 |
| Synonymic references..... | 27 |
| List, by genera, subgenera, species, and varieties, of references in synonymy, with present reference of each..... | 27 |
| Geologic data..... | 98 |
| General geographic and stratigraphic distribution..... | 98 |
| Distribution by species..... | 98 |
| General geographic and stratigraphic distribution of the Cambrian and Ordovician Brachiopoda..... | 98 |
| Summary of Cambrian Brachiopoda..... | 110 |
| Summary of Ordovician Brachiopoda..... | 113 |
| General summary of Cambrian and Ordovician Brachiopoda..... | 113 |
| Detailed geographic distribution..... | 114 |
| Cambrian Brachiopoda..... | 114 |
| North American species..... | 114 |
| European species..... | 120 |
| Asiatic species..... | 121 |
| South American species..... | 122 |
| Australian species..... | 122 |

| Mickwitzia Schmidt..... | 329 |

^a The list of species on pp. 98-109 gives the names of all the species in the order in which they appear in the monograph and also not only the page but the illustration reference and other information. It should therefore be of more value to the student than a mere list of species in these contents, and such a list has accordingly been omitted. The pages upon which the genera and subgenera are described are not shown in the list on pp. 98-109; therefore these are shown here.

CAMBRIAN BRACHIOPODA.

By CHARLES D. WALCOTT.

INTRODUCTION.

PREPARATION AND SCOPE.

It was not until after the preparation of the preliminary memoir on the fauna of the Lower Cambrian or *Olenellus* zone^a that I began to think seriously of undertaking the systematic study of the Cambrian faunas of the world. The second extended contribution was the memoir on the fossil Medusæ,^b after which studies were continued on the Brachiopoda. Administrative duties have greatly interfered with the prosecution of the work, but by taking advantage of all opportunities, both in the field and office, some progress has been made from year to year. The work is not so complete as it might be in its discussion of genera and species, details of evolution, and the relations of the Cambrian brachiopod fauna to Ordovician and later faunas. My main purpose has been to make the results of the investigation of value to the student of Cambrian faunas and to the stratigraphic geologist.

This monograph includes the description of 44 genera, 15 subgenera, 477 species, and 59 varieties of Cambrian Brachiopoda, and of 3 genera, 1 subgenus, 42 species, and 1 variety of Ordovician Brachiopoda. Of the Cambrian forms, 10 genera, 2 subgenera, 21 species, and 1 variety persist into the Ordovician. (See pp. 98-113 for complete tables giving distribution.)

In this paper the Brachiopoda are treated in three ways—historically, geologically, and zoologically. Historically the treatment comprises (1) a bibliography and (2) a table of synonymic reference, giving a completely cross-referenced list of described species with the present generic and specific reference of each. Geologically the distribution of the Brachiopoda is considered under the following headings: (1) General geographic and stratigraphic distribution; (2) detailed geographic distribution; (3) detailed stratigraphic distribution; (4) habitat; and (5) fossil localities. Zoologically the discussion covers (1) the physical characters of the Brachiopoda; (2) their distribution; (3) their evolution; and (4) their classification. Lastly come the detailed descriptions of genera and species and the illustrative plates.

ACKNOWLEDGMENTS.

In the course of the investigations of the Cambrian brachiopods during the past ten years I have received assistance in various forms and degrees from many individuals in all sections of the world where the Cambrian strata and faunas occur. To all I return my most grateful acknowledgment and sincere thanks. If any who have assisted me are overlooked in these acknowledgments, I beg leave to assure them that it is not by intention.

Dr. Ferdinand Schmidt, of the Royal Institution of St. Petersburg, sent many specimens and valuable notes on the range of the species in the Upper Cambrian and Lower Ordovician beds of the Baltic provinces of Russia.

Dr. A. Mickwitz, of Reval, Esthonia, Russia, sent material from the *Obolus* beds of Russia.

^a Walcott, C. D., Fauna of the Lower Cambrian or *Olenellus* zone: Tenth Ann. Rept. U. S. Geol. Survey, pt. 1 1890, pp. 509-763.

^b Walcott, C. D., Fossil Medusæ: Mon. U. S. Geol. Survey, vol. 30, 1898.

Mr. J. F. Nery Delgado, of the Geological Survey of Portugal, presented photographs of several of the Lower Cambrian brachiopods described by him from Portugal, also a specimen of the new form *Delgadella lusitanica*.

Dr. Charles Barrois, of the University of Lille, France, gave information in relation to the Cambrian faunas of Spain and France.

Dr. Karl A. Grönwall, of the Geological Survey of Denmark, made a collection of Cambrian fossils for me in Bornholm, among which were fine representatives of the brachiopods described by him in his memoir on the *Paradoxides* fauna of Bornholm.

Dr. J. F. Pompeckj, of the University of Hohenheim, Wurttemberg, Germany, was always ready to give information and assistance.

Dr. T. H. Holland, director of the Geological Survey of India, generously loaned for study the collection of brachiopods from the Cambrian formations of the Salt Range, and gave me the opportunity of studying and illustrating Doctor Waagen's types.

Prof. Walter Howchin, of the University of Adelaide, South Australia, sent for study and illustration all the types of Cambrian fossils described by Messrs. R. Etheridge, jr., and Ralph Tate.

As a result of the expedition of the Carnegie Institution of Washington to China under the direction of Mr. Bailey Willis, assisted by Mr. Eliot Blackwelder, large collections of fossils were made from many faunal horizons of the Cambrian, and among them the various brachiopods described in this volume.

Dr. W. C. Brögger, of the University of Christiania, Norway, very generously loaned the types described by him in "Die Silurischen Etagen 2 und 3," also duplicate material of Cambrian brachiopods which he had collected at various localities in Norway.

Dr. N. Olof Holst, of the Geological Survey of Sweden, very kindly took charge of the making of collections of Cambrian fossils for me by Mr. G. Schmalensee, a collector of the Survey, and also permitted the sending of specimens for study and in exchange.

Dr. Joh. Chr. Moberg, of Lund, Sweden, both loaned and presented material for study.

Through the courtesy of Dr. Carl Wiman, of Upsala, Sweden, I had the opportunity of studying the Cambrian brachiopods described by him from the North Baltic region. He not only sent me the specimens, but also answered inquiries in relation to certain facts concerning them which did not appear in the text of his report.

I am greatly indebted to the Geological Survey of Canada for the loan of many of the types in the collections of the Survey museum. Prof. J. F. Whiteaves and Dr. Henry M. Ami were especially kind in selecting and forwarding the specimens desired.

Sir William E. Dawson permitted me to look over the collection of the McGill University museum, and later Dr. Frank D. Adams sent specimens of the Cambrian brachiopods in the collection.

For many years before the sale of his collection, Dr. George F. Matthew, of St. John, New Brunswick, frequently loaned me his types and study material, and also when I visited New Brunswick directed me to the most favorable localities for collecting material both in New Brunswick and Cape Breton. When his collections went to the University of Toronto, Prof. W. A. Parks sent to me from them the various types that I needed for study and illustration.

Prof. Alexander Agassiz permitted me to study the collections of Cambrian brachiopods in the Museum of Comparative Zoology, and also to take to Washington and have illustrations made of a number of specimens, especially those from Bohemia.

Prof. J. M. Clarke, director of the New York State Museum, Albany, N. Y., was most courteous in lending material and giving information relating to it.

Mr. W. A. Finkelnburg, of Winona, Minn., sent material from his collection, and also made collections from the "St. Croix sandstone" at several localities in Minnesota which enabled me to add very materially to the description of the Cambrian brachiopods of Minnesota.

Prof. Alpheus Hyatt, of the Boston Museum of Natural History, lent material he collected on the coast of Labrador, and he was always ready to discuss problems connected with the life history and evolution of the Brachiopoda.

To no one am I more indebted than to Prof. Charles Schuchert, of Yale University, whose suggestions and comments, made in response to questions submitted to him, and also as the result of examining the plates and the preliminary draft of the zoological discussion, have been most helpful.

From year to year material for study was brought in by various members of the United States Geological Survey as opportunity offered, and large collections were made in the Cordilleran area of the United States by Mr. S. Ward Loper, of the Wesleyan University museum. I collected personally from various parts of the United States and Canada, England, and Wales, being assisted in the Cordilleran area by Mr. F. B. Weeks and Mr. Lancaster D. Burling.

During the course of the preparation of this monograph I have received from time to time effective assistance from members of the United States Geological Survey, especially those directly acting as my assistants. When studying the Acrotretidæ Dr. George H. Girty selected material for illustration and also made preliminary notes on some of the species. Miss Elvira Wood separated and classified the brachiopods collected in 1905-6, directed the preparation of drawings, and, in 1906, revised the proof of the plates, which were printed at that time.

Mr. Lancaster D. Burling, of the United States National Museum, revised, verified, and tabulated the synonymy and localities and assisted in many ways in the final make-up of the text of the volume from 1907 to 1912.

At my request Mr. E. O. Ulrich, of the United States Geological Survey, carefully read the zoological discussion and made notes that led me to make several modifications, especially in relation to the protrematous genera. I have included in the text his observations on the spondylium.

To Mr. R. S. Bassler, of the United States National Museum, I am indebted for a number of thin sections of the shells of Cambrian brachiopods and a few Ordovician orthoids and for notes on the sections.

The drawings have been prepared mainly by Miss Frances Wieser, of the United States Geological Survey. The plates are the evidence of her faithful work.

HISTORICAL DATA.

BIBLIOGRAPHY.

The following bibliography includes the works referred to in this monograph,^a arranged alphabetically by authors and chronologically under each author:

- AMI, H. M.:
1887. The Ottawa Naturalist, vol. 1, No. 9, 1887 (Dec.), pp. 121-126: Notes on, and the precise geological horizon of, *Siphonotreta scotica* Davidson.
- BARRANDE, J. (see also DE VERNEUIL and BARRANDE):
1848. Naturwissenschaftliche Abhandlungen, gesammelt und durch Subscription herausgegeben von Wilhelm Haidinger, Bd. 2, Abth. 1, No. 5, 1848, pp. 153-256: Ueber die Brachiopoden der silurischen Schichten von Böhmen. 4°. Wien.
1868a. II: Faune silurienne des environs de Hof, en Bavière, 1868 (Dec.), pp. 31-110 (published with I: Répartition du genre *Arethusina* Barrande.) 8°. Prague.

GEOLOGIC DATA.

GENERAL GEOGRAPHIC AND STRATIGRAPHIC DISTRIBUTION.

The distribution of the Brachiopoda, both Cambrian and Ordovician, is set forth in the four tables following. The first (pp. 98-109) gives the general geographic and stratigraphic distribution of the various Cambrian and Ordovician species, arranged zoologically; the second (pp. 110-112) gives a summary of the Cambrian Brachiopoda by genera and by families; the third (p. 113) a summary of the Ordovician Brachiopoda by genera and by families; and the fourth (p. 113) a general summary by families of all the Brachiopoda described in this paper, whether Cambrian or Ordovician.

The question of the systemic reference of some of the formations (e. g., whether the *Orthoceras* limestone and the *Ceratopyge* limestone should be placed in the Ordovician or the passage beds between the Upper Cambrian and Ordovician, or whether the *Ceratopyge* slate, the *Bryograptus* slate, and the *Dictyograptus* slate should be referred to the Upper Cambrian or the Ordovician, etc.) does not appear to be a vital one in connection with this monograph. Whenever possible, however, the localities included in these pages contain the names of the formations represented, and these should enable the student to refer the species to the desired place in the geologic column.

DISTRIBUTION BY SPECIES.

The following table gives the general geographic and stratigraphic distribution of the Cambrian and Ordovician Brachiopoda taken up in this monograph:

General geographic and stratigraphic distribution of the Cambrian and Ordovician Brachiopoda.

SUMMARY OF CAMBRIAN BRACHIOPODA.

The distribution of the Cambrian Brachiopoda is summed up in three tables. The first (pp. 110-111) gives the general geographic and stratigraphic distribution of the genera; the second (p. 112) gives the same information for the families; and the third (p. 112) is a summary of the Cambrian Brachiopoda by genera and species.

Summary of Cambrian Brachiopoda by genera.

^a This table includes all Ordovician species taken up in the monograph. With the exception of three genera, one subgenus, forty-two species, and one variety all of these pass up from the Cambrian. (See pp. 122-123 for a list of the Ordovician forms taken up in this monograph.)

GENERAL SUMMARY OF CAMBRIAN AND ORDOVICIAN BRACHIOPODA.

The following table gives a general summary of the genera, subgenera, species, and varieties, both Cambrian and Ordovician, in each of the families taken up in this monograph:

General summary of Cambrian and Ordovician Brachiopoda.

DETAILED GEOGRAPHIC DISTRIBUTION.

In the following lists the various species of Cambrian Brachiopoda are listed by continents, as they occur in the various faunal provinces of Cambrian time in North America and in other countries. The record of the local distribution of each species will be found at the end of the description of the species.

The tables are arranged under the following heads, the species being zoologically arranged under each head:

1. North American species of Cambrian Brachiopoda (p. 114).
2. European species of Cambrian Brachiopoda (p. 120).
3. Asiatic species of Cambrian Brachiopoda (p. 121).
4. South American species of Cambrian Brachiopoda (p. 122).
5. Australian species of Cambrian Brachiopoda (p. 122).
6. North American species of Ordovician Brachiopoda (p. 122).^a
7. European species of Ordovician Brachiopoda (p. 123).^a

CAMBRIAN BRACHIOPODA.

NORTH AMERICAN SPECIES.

Geographic distribution of North American species of Cambrian Brachiopoda.

NOTE.—The letters placed opposite each species in the various columns denote the State or province in which the species occurs; for instance, a "C" in column 2 under A indicates that the species occurs in Cape Breton, "CN" indicates that it occurs in both Cape Breton and New Brunswick.

DETAILED STRATIGRAPHIC DISTRIBUTION OF CAMBRIAN AND ORDOVICIAN BRACHIOPODA.

The following table includes, arranged alphabetically by States or countries, more or less detailed information concerning the stratigraphic distribution of the different species of Cambrian and Ordovician Brachiopoda.

The data available for the foreign species were not sufficient to warrant greater detail than that secured by the use of generalized sections, and there has been no attempt to keep the species from any one section in a distinct column. Doubtful correlations are indicated by a question mark after the locality number.

For some of the regions in North America typical fossiliferous sections have been introduced, giving in an adjoining column the species collected from the various horizons in the section and in a third column the species collected at other places in the same general area. In such tables the stratigraphic arrangement of the second column is fairly accurate; that of the third may contain errors in correlation and must be regarded as merely approximate. Each specific name is followed by the number of the locality at which it occurs, and the list of localities on pages 161-291 will furnish the student with all known information as to the association and the stratigraphic and geographic position of the species in question.

The numbers of the different localities identified from a given formation, State, country, or place may be found by referring to the index.

*Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda.^a***Alabama.**

See Tennessee, Georgia, and Alabama, where the horizons are more or less closely differentiated and correlated, with complete lists of localities and included species.

Alberta.

See British Columbia: Mount Bosworth section, where the Alberta localities are shown in their approximate stratigraphic position.

Arizona.

One of the Arizona localities (75) has been assigned to the Upper Cambrian; 74b occurs high up in the Tonto group, but has been entered as Middle Cambrian; and the remainder (see index for numbers) occur at various more or less closely related horizons in the "Tonto" sandstone.

Bohemia.

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

British Columbia: Mount Bosworth.

| Mount Bosworth section. [Walcott, 1908f, pp. 204-217.] | Localities and species in the Mount Bosworth section. | Other localities and species in British Columbia and Alberta shown in their approximate stratigraphic position. |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <p>The Mount Bosworth section is exposed north of Hector, British Columbia, on the Continental Divide north of the Canadian Pacific Railway.</p> <p>The general dip of the strata is to the northwest 20°; strike, N. 30° E.</p> <p>The section is continuous except for the displacement between the Paget and Bosworth formations of the Upper Cambrian. That this does not cut out any considerable thickness of strata is proved by the unbroken section in the cliffs of Mount Daly 3 miles to the north. Only the upper part of the St. Piran sandstone is exposed on Mount Bosworth; the remainder of the section shown on pages 131 and 132 was measured in the vicinity of lakes Louise and Agnes, nearly 5 miles to the southeast.</p> <p>The summit of the section is on the west spur (Sherbrooke ridge) of Mount Bosworth overlooking Sherbrooke Lake. The highest beds are on the south summit of the ridge, and from their lithologic character and the presence of obscure fossils that suggest <i>Ophileta</i> of the Lower Ordovician the upper 110 feet of strata is tentatively referred to the Ordovician system.^a The strata near the summit are much broken up owing to a fault line that crosses the ridge.</p> <p style="text-align: center;">ORDOVICIAN.^a</p> <p>1. Massive-bedded gray and bluish-gray arenaceous limestone, with thin layers, irregular stringers, and nodules of dark chert..... Feet. 110</p> | | |
| <p style="text-align: center;">UPPER CAMBRIAN.</p> <p><i>Sherbrooke limestone</i> [Walcott, 1908a, p. 2]:</p> <p>1. Massive-bedded bluish-gray limestone, with some cherty matter in the form of small nodules and stringers; also irregular partings and fillings of annelid borings by gray dolomitic limestone, weathering buff..... 175</p> | <p>Annelid borings and trails. Fragments of undeterminable trilobites.</p> | |
| <p>2a. Gray oolitic limestone in thick layers, with bluish banded limestone intercalated at irregular intervals. The banded appearance of the nonoolitic layers is owing to the buff-weathering of the thin dolomitic layers..... 190</p> | <p><i>Crepicephalus</i>. <i>Pteroccephalia</i>?. <i>Ptychoparia</i>.</p> | |
| <p>2b. Greenish-drab and gray siliceous shales with interbedded oolitic limestone in bands of layers from 6 inches to 4 feet thick; also a few bands of thick-bedded bluish-gray limestone that breaks up into shaly limestone on weathering.. 335</p> | <p>57d, 58f. In green shales near summit: <i>Lingulella issc</i>—57d. In oolitic layers: <i>Agnostus</i> sp. undt. <i>Ilænurus</i>. <i>Ptychoparia</i>. In limestone: <i>Obolus</i> sp.—58f.</p> | |
| <p>2c. Gray oolitic limestone with thin bands of interbedded shaly blue-gray limestone. Gray dolomitic buff-weathering flattened nodules, stringers, and thin layers of limestone occur in a very irregular manner..... 65</p> | <p><i>Ilænurus</i>. <i>Agnostus</i>. <i>Ptychoparia</i>. <i>Bathyurus</i>-like pygidia.</p> | |
| <p>3. Arenaceous dolomitic steel-gray limestone, weathering light gray and buff gray..... 610</p> <p>The line of demarcation between 3 and the bluish-gray limestones below is irregular. The gray beds of 3 extend along the cliff and abruptly change to bluish gray. In the upper 100 feet of 3 irregular masses of bluish-gray limestone occur like great lentils, as though they were cores left in the general alteration (dolomitization) of the strata.</p> <p>Total of Sherbrooke limestone..... 1,375</p> | | |
| <p><i>Paget limestone</i> [Walcott, 1908a, p. 3]:</p> <p>1. Massive-bedded dark bluish-gray limestone forming base of cliff on the west side of the amphitheater on the west slope of Mount Bosworth and, with 3 of Sherbrooke limestone, the upper cliffs of Paget Peak and Mount Daly..... 60</p> <p>2. Massive beds of oolitic limestone with irregular interbedded bands of green siliceous shale. Thin layers, irregular stringers, and nodules of gray buff-weathering dolomite occur in the oolitic limestones..... 300+</p> <p>Base covered by talus slope on line of the section. It is well exposed on the southeast face of Mount Daly and Paget Peak. The thickness is placed at 300 feet, which I think is less than the total thickness. Over 200 feet was measured.</p> <p>Total of Paget limestone..... 360+</p> | <p><i>Hyalolithes</i>. <i>Agnostus</i>. <i>Crepicephalus</i>.</p> | |

^a During the field season of 1911 these beds were examined by Mr. J. A. Allan and Mr. L. D. Burling, who found, in the uppermost portion, fossils similar to those in 2b of the Sherbrooke limestone. This made it possible to place between the new Sherbrooke and the true Ordovician a series of nearly 4,000 feet of Upper Cambrian shales and limestones referred by Mr. Allan to the Chancellor and Ottetail formations, respectively. (See Walcott, 1912, Smithsonian Miscellaneous Collections, vol. 57, No. 7, pp. 229-231.)

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

British Columbia: Mount Bosworth—Continued.

| Mount Bosworth section. [Walcott, 1908f, pp. 204-217.] | Localities and species in the Mount Bosworth section. | Other localities and species in British Columbia and Alberta shown in their approximate stratigraphic position. |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UPPER CAMBRIAN—continued. | | |
| <i>Bosworth formation</i> [Walcott, 1908a, p. 3]: ^a | | |
| 1. Massive-bedded gray and bluish-gray arenaceous dolomitic limestone. Several bands of steel-gray, yellowish buff-weathering bands of strata occur in the lower half of 1. This formation forms the base of the high cliffs on the southeast face of Mount Daly and Paget Peak. The lower portion of 1 was measured and the upper parts estimated. The thickness given is probably 100 feet or more less than the actual thickness. | Feet. 600+ | |
| 2a. Shaly and thin-bedded gray and dove-colored, compact, fine-grained dolomitic limestone weathering buff and light gray. Thicker layers occur in bands from 1 to 6 feet thick. 422 | | |
| 2b. Greenish siliceous shale with thin interbedded layers of siliceous, compact, gray limestone. 48 | | At about this horizon in the Castle Mountain section, 20 miles southeast of Mount Bosworth, small trilobite heads of the genera <i>Ptychoparia</i> and <i>Solenopleura</i> occur in a band of gray and bluish-black limestone, and, just below, fragments of a species of <i>Obolus</i> . |
| 2c. Limestones similar to 2a. 517 | 987 | |
| 3. Variable arenaceous shales with alternating bands of color—greenish, deep red, buff, yellow, and gray. Numerous mud cracks and ripple-marks occur on many of the layers. | 268 | |
| Total of Bosworth formation. | 1,855+ | |
| Total Upper Cambrian. | 3,590+ | |
| MIDDLE CAMBRIAN. | | |
| <i>Eldon limestone</i> [Walcott, 1908a, p. 3]: | | |
| 1a. Irregularly bedded gray siliceous and arenaceous limestone in thick layers above and thin layers below; at 192 feet from the base a bed of bluish-black limestone is fossiliferous. Above the fossiliferous bed the strata become more massive, arenaceous, steel gray in color, and weather to a light gray. 410 | | 192 feet above the base: <i>Agnostus</i> sp. <i>Ptychoparia</i> , 2 species. <i>Bathyriscus</i> -like pygidium. |
| 1b. Light and dark gray thin-bedded arenaceous limestone weathering light gray. 110 | | |
| 1c. Massive-bedded siliceous, fine-grained, compact, dark bluish-gray limestone. 197 Two yellowish buff-weathering bands of limestone 2 to 3 feet thick stand out in color on the face of cliffs. | | Near the summit: <i>Billingstella</i> ? <i>Ncolenus</i> -like pygidium. |
| 1d. Massive-bedded limestone much like that of 1c. 71 | 788 | |
| 2. Thin-bedded bluish-gray limestone with irregular layers and stringers of gray buff-weathering dolomitic limestone. 95 At 24 feet from the base a shaly bluish-gray siliceous limestone about 2 feet thick is interbedded. | | 35g. In shaly limestone: <i>Obolus mccoanelli</i> var.— 35g. <i>Obolus membranaceus</i> — 35g. <i>Isoxys cf. argentea</i> —35g. <i>Ptychoparia</i> , 3 species—35g. |
| 3. Massive-bedded dark-gray arenaceous limestone. 190 | | |

^a This formation reminds me, in lithologic character and appearance, of strata of the upper portions of the Algonkian Belt series of Montana. No traces of life were observed and the shaly, banded character of the beds is very striking.

(See 35k, 57f, 57j, 58j, and 58r, pp. 198 and 207-210, for additional associated forms.)</p> |
| | | <p>14s.</p> <p>At Mount Stephen, about 7 miles southwest of Mount Bosworth, a siliceous shale <i>b</i> occurs at the summit of the Stephen formation, in which the following unusually rich fauna occurs:</p> <p><i>Hyolithellus flagellum</i> (Matthew) [1899, p. 40]. <i>Hyolithellus annulatus</i> (Matthew) [1899, p. 42]. <i>Orthotheca corrugata</i> Matthew [1899, p. 42]. <i>Orthotheca major</i> Walcott [1908c, p. 246, Pl. I, fig. 11]. <i>Hyolithes carinatus</i> Matthew [1899, p. 42]. <i>Hyolithes</i> sp. <i>Stenothecha wheeleri</i> Walcott [1908c, p. 245, Pl. I, fig. 7]. <i>Platyceras romingeri</i> Walcott [1889c, p. 442]. <i>Platyceras bellionus</i> Walcott [1908c, p. 246, Pl. I, fig. 13]. <i>Acrotreta depressa</i> (Walcott) [1889c, p. 441]. <i>Micromitra (Iphidella) pannula</i> (White) [1874, p. 6]. <i>Obolus mcconnelli</i> (Walcott) [1889c, p. 441]. <i>Obolus septalis</i> Walcott [1905a, p. 331]. <i>Nisusia alberta</i> Walcott [1889c, p. 442]. <i>Philhædra columbiana</i> (Walcott) [1889c, p. 441]. <i>Scenella varians</i> Walcott [1886b, p. 127].</p> |

^a This is the locality containing the beautifully preserved annelids, medusæ, holothurians, crustaceans, etc., now being described and illustrated in volume 57 of the Smithsonian Miscellaneous Collections.

^b The name *Ogygopsis* zone is applied to the local development of arenaceous and calcareous shale at the summit of the Stephen formation on the northwest slope of Mount Stephen. The shale band (lentile) has a maximum thickness of about 150 feet. It thins out to the northeast and is faulted out to the southwest. At its maximum thickness, 2,800 feet above Field, it carries immense numbers of trilobites, especially *Ogygopsis klotzi* (Rominger), *Bathyuriscus rotundatus* (Rominger), *Neolenus serratus* (Rominger), *Zacanthoides spinosus* (Walcott), and, in addition, sponges, cystids, brachiopods, pteropods, and gastropods. The shale is less rich in fossils one-fourth mile northeast on the strike; also to the northwest. Lentiles of gray quartzitic sandstone and siliceous gray limestone occur in the shale, and the entire band appears to be a lentile between the thin-bedded blue limestones and the superjacent massive arenaceous limestone formation. There is no trace of the *Ogygopsis* zone at the same horizon on Castle Mountain 20 miles east-southeast. On Mount Field it is represented by the Burgess shale, Locality 35k.

There is a sharp anticline, with a northeast-southwest axis, in the shale and the thin-bedded limestones beneath, on the northwest slope of Mount Stephen. The southeast limb is crushed and the beds are largely faulted out against the massive arenaceous limestone before reaching the amphitheater at the head of Field Brook. On the northwest limb the shales are unaltered and slope down the side of the mountain for 1,800 feet, thus affording a great exposure of the shale and contained fossils.

| LOWER CAMBRIAN—continued. | | |
| <i>Mount Whyte formation</i> —Continued. 2. Gray and brownish-gray sandstone in thin and massive layers Feet. 31 | <i>Hyolithes</i> . <i>Agraulos</i> . | On Mount Stephen, at this horizon, there were found: <i>Microdiscus</i> sp. undt. <i>Olenellus</i> sp. undt. (fragments). <i>Ptychoparia</i> sp. undt. <i>Protypus</i> sp. undt. |
| 3. Siliceous shale with a few interbedded thin layers of compact hard gray sandstone 115 | 35c. On the south slope of Mount Bosworth two drift blocks of siliceous shale, supposed to be from this horizon, were found, from which the following species were collected: <i>Micromitra</i> (<i>Paterina</i>) <i>wapta</i> —35c. <i>Obolus parvus</i> —35c. <i>Acrothel colleni</i> —35c. <i>Wimacella simplex</i> —35c. <i>Agraulos</i> sp.—35c. <i>Ptychoparia</i> sp.—35c. <i>Albertella bosworthi</i> —35c. <i>Albertella helena</i> —35c. <i>Bathyuriscus</i> sp.—35c. | 35e. In the Lake Agnes section, 5 miles southeast of Mount Bosworth, the fauna of about this horizon includes: <i>Micromitra</i> (<i>Paterina</i>) <i>wapta</i> —35e. <i>Obolus parvus</i> —35e. <i>Hyolithes billingsi</i> —35e. <i>Olenopsis</i> n. sp.—35e. <i>Ptychoparia</i> , 3 species.—35e. <i>Albertella</i> sp. undt.—35e. <i>Bothyuriscus</i> —35e. <i>Olenellus gilberti</i> —35e. On Mount Stephen, at about the same horizon, the following were found: <i>Hyolithes billingsi</i> . <i>Secnella varians</i> . <i>Olenopsis</i> n. sp. |
| 4. Interbedded layers of gray fossiliferous limestone and greenish-gray siliceous shale 20 Total of Mount Whyte formation 390 | 35h. <i>Nisusia festinata</i> —35h. <i>Secnella varians</i> —35h. <i>Hyolithellus</i> —35h. <i>Ptychoparia</i> —35h. <i>Agraulos</i> —35h. <i>Protypus</i> n. sp.—35h. <i>Olenellus canadensis</i> —35h. <i>Olenellus gilberti</i> —35h. | 35f. At this horizon on Mount Stephen the following were found: <i>Micromitra</i> (<i>Iphidella</i>) <i>pannula</i> —35f. <i>Kutorgina cingulata</i> —35f. <i>Kutorgina</i> sp. undt.—35f. <i>Acrotreta sagittalis taconica</i> —35f. <i>Nisusia festinata</i> —35f. <i>Hyolithes billingsi</i> —35f. <i>Secnella varians</i> —35f. <i>Protypus</i> n. sp.—35f. <i>Agraulos</i> sp. undt.—35f. <i>Ptychoparia</i> , 3 sp. undt.—35f. <i>Olenellus canadensis</i> —35f. |
| Bow River group. | | |
| <i>St. Piran sandstone</i> [Walcott, 1908a, p. 4]: 1a. Siliceous and arenaceous greenish-colored shales in layers 1 to 3 inches in thickness interbedded in shaly and thin-bedded gray and brownish-gray sandstone, with a thick layer of compact gray sandstone near the top 68 | | |
| 1b. Irregularly bedded brownish, dirty-gray, and occasionally purplish-colored sandstones, more or less compact and quartzitic, in massive and thin layers that break down readily on slopes 310 | Annelid trails and borings (<i>Scolithus</i>). <i>Hyolithes</i> . <i>Olenellus canadensis</i> ?. <i>Ptychoparia</i> , 2 species. | 60b. <i>Obolella vermillionensis</i> —60b. <i>Wanneria gracile</i> —60b. |
| 1c. Massive-bedded compact light-gray and pinkish quartzitic sandstones 125 503 | Annelid trails and borings (<i>Scolithus</i>). <i>Hyolithes</i> . <i>Olenellus canadensis</i> ? | |
| In the Lakes Louise and Agnes section, about 5 miles southeast of Mount Bosworth, the total thickness of the <i>St. Piran</i> sandstone is 2,705 Below the <i>St. Piran</i> the following section occurs: <i>Lake Louise shale</i> [Walcott, 1908a, p. 5]: 1. Compact gray siliceous shale 105 | 35d. Annelid trails—35d. <i>Cruziona</i> —35d. <i>Micromitra</i> (<i>Iphidella</i>) <i>louise</i> —35d. | |

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

British Columbia: Mount Bosworth—Continued.

| Mount Bosworth section. [Walcott, 1908], pp. 204-217.] | Localities and species in the Mount Bosworth section. | Other localities and species in British Columbia and Alberta shown in their approximate stratigraphic position. |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| LOWER CAMBRIAN—continued. Bow River group—Continued. | | |
| <i>Fort Mountain sandstone:</i> ^a 1. Thin and thick layers of gray, quartzitic, brownish weathering, compact sandstones (estimated)..... | <i>F. feet.</i> 600+ | |
| Total Lower Cambrian..... | 3,800+ | |
| Total Cambrian..... | 12,353+ | |

^a In 1908 [Walcott, 1908a, p. 5] these quartzitic sandstones were described as the "Fairview formation." As that name, however, is preoccupied in American nomenclature, and as the lower part of the formation has since been found exposed at several places on the east side of the Bow River Valley, it has been decided to apply the name Fort Mountain sandstone to the whole, from the typical exposures on Fort Mountain. The formation is here composed of 2,700 feet of sandstones similar to the 600 feet of sediments to which the name "Fairview" was applied, and a basal bed of massive conglomerate nearly 200 feet thick. At this locality the Fort Mountain formation is unconformably underlain by pre-Cambrian rocks.

California.

See Nevada, Barrel Spring section, where the California localities are shown in their approximate stratigraphic position.

Cape Breton and New Brunswick.

For the strata above the Etcheminian a generalized section only has been used. The Cape Breton localities have, however, been kept distinct from those in the vicinity of St. John. The Acadian is not represented in the brachiopod collections from Cape Breton. The Etcheminian is so well developed and so fossiliferous on Dugald Brook that Matthew's section is copied and the fossils from the brook are kept separate from those occurring elsewhere.

| Section. | Localities and species occurring in Cape Breton arranged in their approximate stratigraphic position. | Localities and species occurring in the vicinity of St. John, New Brunswick, arranged in their approximate stratigraphic position. |

| LOWER CAMBRIAN. ^a | | |

^a Fossils from the Lower Cambrian have been identified at but two localities (3a and 301v), and these are on Hanford Brook, near St. John, New Brunswick. The Lower Cambrian is not represented in the brachiopod collections from Cape Breton.

Colorado.

Most of the Colorado forms occur in the siliceous beds of the Lower Ordovician. Three localities (360g-i) have been identified from the Upper Cambrian and two (3g and 360d) from the Middle Cambrian. For the numbers of all the localities see the index.

Denmark.

See Sweden, Denmark, Finland, and Norway, where the horizons are more or less closely differentiated and correlated, with complete lists of localities and included species.

England, Scotland, and Wales.

| <i>Lamotte sandstone.</i> | |

Montana and Wyoming.

The sedimentation in Montana and northwestern Wyoming exhibits so many peculiarities that correlation is difficult, even between sections only a few miles apart. The Wolsey shale occupies a position immediately above a sandstone in the Little Belt Mountains and is Middle Cambrian in age. It can thus be closely correlated with the similarly situated Flathead shales of Peale, which are also Middle Cambrian. On Dearborn River, however, a shale which occupies the same stratigraphic position [see Walcott, 1908f, pp. 202–203] carries a typical Lower Cambrian fauna in its lower part and Middle Cambrian in its upper layers. The sandstone underlying the Dearborn River shale horizon is Lower Cambrian in age, and that underlying Peale's Flathead shales has been found to contain a fairly well developed Middle Cambrian fauna.

The Gallatin formation of Peale has a very wide geographic distribution, and collections have been made at many localities. The various horizons can not be differentiated, but the faunas show clearly that his Gallatin is in part Upper Cambrian and in part Middle Cambrian. A limestone in the Phillipsburg quadrangle that is believed to be the equivalent of the Yogo limestone of the Little Belt Mountains has been found to contain both Middle and Upper Cambrian fossils.

The localities (see index for numbers) give all the known data as to the stratigraphy of the different collections.

Nevada: Barrel Spring.

|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| A section of Lower Cambrian strata studied by Mr. F. B. Weeks near Barrel Spring, 16 miles south of the town of Silver Peak, Nevada, is much like that east of Waucoba Springs, and has about the same fauna at various horizons in it. LOWER CAMBRIAN. 1. Massive blue-mottled limestone, with 50 feet of sandy limestone in the middle of the series. 737 | <i>Archæocyathus</i> and allied forms occur throughout. | |

^a It has been agreed, but too late for any other correction than the insertion of this footnote, that the “Edgewise beds” should be placed in the Upper Cambrian.

^b Three scattering localities have been identified as Middle Cambrian, and eight localities were collected from the Emigrant formation (Upper Cambrian) of Turner in the Silver Peak district. See index for locality numbers.

New York.

Five or six of the New York localities are scattering; the remainder may be separated into two groups, Upper Cambrian (Potsdam) and Lower Cambrian. In each of these divisions little stratigraphic differentiation is possible, but the localities (see index for numbers) give all known stratigraphic data.

Norway.

See Sweden, Denmark, Finland, and Norway, where the horizons are differentiated and correlated, with complete lists of the localities and included species.

Nova Scotia.

See Cape Breton and New Brunswick, where the horizons are closely differentiated and correlated, with complete lists of localities and included species.

Oklahoma: Arbuckle Mountains.

For the Arbuckle limestone the section 7 miles north of Springer, on the south side of the Arbuckle Mountains, is used, and for the Reagan sandstone a section measured by E. O. Ulrich in sec. 2, T. 4 N., R. 13 W., on the north side of the Arbuckle Mountains, 15 miles northwest of Fort Sill.

| Springer section, south side of Arbuckle Mountain. | Localities and species in the Springer section. | Other localities and species in Oklahoma in their approximate stratigraphic position. |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|---------------------------------------------------------------------------------------|
| ORDOVICIAN. | | |
| <i>Arbuckle limestone:</i> ^a | | |
| 1. Compact dolomitic limestone with occasional calciferous fossils, nearly Feet. 4,500 | | |
| 2. Rather thin-bedded, mostly compact, gray or blue limestone, with grano-crystalline layers in lower half containing fossils, mainly trilobites. 250 | | |
| 3. Crystalline limestone weathering dark and breaking down into rough howldery jointed masses, in which the sedimentation is much obscured. Upper member grano-crystalline and gray; middle member with white and pink marble; lower member grano-crystalline and dark gray to white. 305 | | |

^a The section of the Arbuckle limestone was measured on the south side of the Arbuckle Mountains, 7 miles north of Springer.

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

Oklahoma: Arbuckle Mountains—Continued.

| Springer section, south side of Arbuckle Mountains. | Localities and species in the Springer section. | Other localities and species in Oklahoma in their approximate stratigraphic position. |

| 4. Heavy bedded compact gray limestone..... | 4 | |
| 5. Thin-bedded shaly limestone with fossils..... | 4 | 12m. <i>Obolus tetonensis ninus</i> —12m. <i>Lingulella similis</i> —12m. <i>Eoorthis remnicha texana</i> —12m. |
| 6. Heavy bedded compact gray limestone..... | 4 | |
| 7. Thin-bedded shaly and clayey limestone, often yellow, with some limestone conglomerate; no fossils..... | 0-10 | |
| Section measured in sec. 2, T. 4 N., R. 13 W., north side of Arbuckle Mountains, by E. O. Ulrich. | | |
| UPPER CAMBRIAN. | | |
| <i>Reagan sandstone:</i> ^a | <i>Feet.</i> | |
| 1. Highly calcareous sandstone, with numerous pure crystalline limestone lenses and layers containing fossils..... | 175 | |
| (125 feet above the base.) | | 5u. <i>Obolus tetonensis ninus</i> —9u. <i>Lingulella similis</i> —9u. <i>Eoorthis indianola</i> —9u. <i>Eoorthis wichitaensis</i> —9u. <i>Syntrophia primordialis</i> —9u. 9q ¹ , 9s, 9w, 12n, 12p ¹ . <i>Obolus tetonensis ninus</i> —9q, 9s, 12n, 12p. <i>Lingulella similis</i> —9s, 12n, 12p. <i>Lingulella ora</i> —9q. <i>Lingulella (Lingulepis) acuminata</i> —9q, 9s, 12n, 12p. <i>Linnarssonella girtyi</i> —9q, 12p. <i>Acrotreta curvata</i> —12p. <i>Acrotreta microscopica</i> —12n, 12p. <i>Acrotreta ulrichi</i> —12p. <i>Eoorthis indianola</i> —9w, 12n, 12p. <i>Eoorthis remnicha</i> —12n, 12p. <i>Eoorthis remnicha texana</i> —12n. <i>Eoorthis wichitaensis</i> —9q, 9s, 12n, 12p. <i>Eoorthis wichitaensis laeviusculus</i> —12n, 12p. <i>Syntrophia primordialis</i> —12n. |
| (100 feet above the base.) | | 9t. <i>Obolus matinalis</i> —9t. <i>Obolus tetonensis ninus</i> —9t. <i>Lingulella similis</i> —9t. <i>Acrotreta microscopica</i> —9t. <i>Eoorthis indianola</i> —9t. 12k. <i>Obolus tetonensis ninus</i> —12k. <i>Lingulella similis</i> —12k. <i>Acrotreta microscopica</i> —12k. <i>Eoorthis indianola</i> —12k. <i>Eoorthis wichitaensis</i> —12k. <i>Eoorthis remnicha texana</i> —12k. <i>Eoorthis wichitaensis laeviusculus</i> —12k. |
| (90 feet above the base.) | | 9p. <i>Obolus tetonensis ninus</i> —9p. <i>Lingulella ora</i> —9p. <i>Linnarssonella girtyi</i> —9p. 9x. <i>Dicclomus politus</i> . |
| (45 feet above the base.) | | 12s. No brachiopods. Trilobites not studied. 9v ¹ . <i>Lingulella (Lingulepis) acuminata</i> —9v. <i>Linnarssonella girtyi</i> —9v. |
| 2. Originally massive calcareous sandstone, now leached into laminar, favose masses, forming small bluffs..... | 25 | |
| (Beds between 2 and 3 are fossiliferous.) | | 9r. <i>Obolus tetonensis ninus</i> —9r. <i>Lingulella similis</i> —9r. <i>Linnarssonella girtyi</i> —9r. <i>Acrotreta microscopica</i> —9r. |
| 3. Whitish crystalline limestone, almost made up of fragments of large eystids. With the limestone small lenses and layers of glauconitic sandstone are interpolated..... | 24 | |
| Base formed of a glauconitic grit 20 feet thick, containing several layers of porphyry pebbles and resting on porphyry. | | |

^a The section of the Reagan sandstone was measured on the north side of Arbuckle Mountains, in sec. 2, T. 4 N., R. 13 W. The Reagan is much more fossiliferous and has a greater development in the section northwest of Fort Sill, in Comanche County, than it has on the south side of the Arbuckle Mountains, in Carter County.

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

Ontario.

See Quebec, Ontario, and Labrador for general discussion of stratigraphy.

Pennsylvania.

All but two of the Pennsylvania localities (see index for numbers) are from approximately the same horizon in the Lower Cambrian. One locality (346b) is from the Upper Cambrian and one (48d) from the Middle Cambrian.

Quebec, Ontario, and Labrador.

Three general horizons from Quebec and Ontario are represented in the collections: An Ordovician (Chazy?), an Upper Cambrian equivalent to the Potsdam of New York, and a Lower Cambrian in limestone pebbles in a conglomerate. The Lower Cambrian forms may be compared with those occurring in localities 392a, 392c, and 392I, all at the Straits of Belleisle, Labrador. See index for numbers of all localities in Quebec, Ontario, and Labrador.

Scotland.

See England, Scotland, and Wales, where the horizons are more or less closely differentiated and correlated, with complete lists of localities and included species.

South Dakota and Wyoming.

Three of the localities (302e, 302p, and 302u) occur in the upper part of the Deadwood formation and have been referred to the Upper Cambrian; the remainder (see index for numbers) occur in the Middle Cambrian at various more or less closely related horizons in the Deadwood formation. (See also Montana and Wyoming.)

Sweden, Denmark, Finland, and Norway.

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

Texas.

The Texas localities are from the Upper Cambrian, at about the stratigraphic horizon of the Reagan sandstone of the Oklahoma section.

Utah: Blacksmith Fork, Cache County.

| Blacksmith Fork section. [Walcott, 1908f, pp. 190-200.] | Localities and species in the Blacksmith Fork section. | Other localities and species in Utah and Idaho shown in their approximate stratigraphic position. |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| <p>The Blacksmith Fork section is located in Blacksmith Fork Canyon, on the east side of Cache Valley, in the Wasatch Mountains, between Ute and Logan Peaks, about 10 miles east of Hyrum, in northern Utah.</p> <p>This section is 230 miles northeast of the House Range section (Utah) and is north of the greater effect of the pre-Cambrian Uinta Mountain uplift and island. The character of the sediments derived from the Uinta area is shown by the continuation of the arenaceous deposits up to the middle of Middle Cambrian time, whereas in the House Range section the arenaceous deposits cease before the Middle Cambrian fauna appears. It is not until after the Belt Mountain and Kintla (of the 49th parallel) uplifts to the north are passed that the order of sedimentation as shown in the Mount Bosworth section is again of the type of the House Range section.</p> <p style="text-align: center;">ORDOVICIAN.</p> <p style="text-align: right;">Feet.</p> <p>1. Dark, bluish-black, and gray limestone. In the basal bed immediately above the Cambrian a fine fauna occurs. The limestone is of the same character as that of the Upper Cambrian for 190 feet below, and, except for the change in the fauna, there is no break in the section. One of the characters common to the Cambrian and the superjacent Ordovician is the presence in most layers of flattened concretionary nodules and stringers from a minute size up to 6 or 8 cm. or more in diameter; the large ones rarely exceed 3 to 10 mm. in thickness.</p> | <p>185z. <i>Eoorthis desmopleura</i>—185z. <i>Syntrophia nundina</i>—185z. <i>Orthoceras</i>—185z. <i>Endoceras</i>—185z. Fragments of trilobites—185z.</p> | <p>105x? <i>Obolus (Westonia) elongatus</i>—105x.</p> |
| <p style="text-align: center;">UPPER CAMBRIAN.</p> <p><i>St. Charles limestone</i> [Walcott, 1908a, p. 6]:</p> <p>1. Dark, bluish-gray, and gray limestone in layers varying from 1 to 20 inches in thickness. Many of the layers are almost made up of flattened concretions varying from a minute size to 6 or 8 cm.</p> <p style="text-align: right;">190</p> | <p>54b, 54c, 54d. 25 feet below the top: <i>Lingulella manticola</i>—54b. <i>Eoorthis desmopleura</i>—54b. <i>Syntrophia nundina</i>—54b. <i>Dicelloccephalus</i>—54b. 105 to 125 feet below the top: <i>Schizambon typicalis</i>—54c. <i>Eoorthis desmopleura</i>—54c. <i>Eoorthis newberryi</i>—54c. <i>Syntrophia nundina</i>—54c. <i>Solenopleura</i>—54c. <i>Menocephalus</i>—54c. <i>Ilkenurus</i>—54c. 20 to 30 feet above base: <i>Lingulella (Lingulepis) acuminata</i>—54d. <i>Eoorthis desmopleura</i>—54d. <i>Eoorthis newberryi</i>—54d. <i>Agnastus</i>—54d. <i>Solenopleura</i>—54d. <i>Menocephalus</i>—54d. <i>Asaphus?</i>—54d.</p> | <p>54r, 329a. <i>Eoorthis desmopleura</i>—54r. <i>Syntrophia nundina</i>—329a.</p> |
| <p>2a. Massive-bedded dark lead-gray arenaceous cliff-forming limestone, becoming thinner bedded in the lower 50 feet.</p> <p style="text-align: right;">195</p> | | |
| <p>2b. Massive-bedded gray arenaceous limestone with a few irregular cherty layers which extend down 85 feet, just below which the dark arenaceous limestone for a thickness of about 15 feet is almost made up of round concretions 2 to 4 mm. in diameter.</p> <p style="text-align: right;">100</p> | | |
| <p>2c. Gray siliceous and arenaceous limestone in layers one-half inch to 6 inches thick, occurring in massive bands. Light-gray chert fills large and small annelid borings, and it also occurs as flattened stringers in the line of the bedding and in the layers.</p> <p style="text-align: right;">85</p> | <p>54j. <i>Obolus (Westonia) iphis</i>—54j. <i>Lingulella desiderata</i>—54j.</p> | |
| <p>2d. Massive-bedded arenaceous limestone, forming broken cliffs. A few cherty nodules occur near the top, and the lower 50 feet has many irregular oval cherty nodules and stringers of chert coincident with the bedding.</p> <p style="text-align: right;">397</p> <p style="text-align: right;">777</p> | | |

| 1c. Same as 1a (estimated)..... | 1,200+ | |
| Total of Brigham quartzite..... | 1,232 | |
| Total Middle Cambrian ^a | 5,420+ | |
| Total Cambrian..... | 6,647+ | |

Utah: House Range, Millard County.

| House Range section. [Walcott, 1908f, pp. 173-185.] | Localities and species in the House Range section. | Other localities and species in Utah and Nevada shown in their approximate stratigraphic position. |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The House Range section lies east and west of Antelope Springs and east-southeast and south of Marjum Pass, House Range, Millard County, Utah. It begins at the top of Notch Peak, the highest point on the House Range south of Marjum Pass. | | |
| ORDOVICIAN. | | |
| Banded thin-bedded bluish-gray and purplish limestone resting conformably on the Cambrian..... | Feet. 285 | 105t. <i>Obolus</i> (<i>Westonia</i>) <i>notchensis</i> —105t. <i>Eoorthis desmopleura</i> —105t. <i>Raphistoma</i> sp., etc.—105t. |
| UPPER CAMBRIAN. | | |
| <i>Notch Peak limestone</i> [Walcott, 1908a, p. 9]: b | | |
| 1a. Gray arenaceous limestone in thick layers and bands of thin layers. Irregular nodules and thin layers of dark-gray chert weathering dark brown occur at irregular intervals for 350 feet below the summit. A few thin cherty layers $\frac{1}{2}$ to $\frac{1}{4}$ inch thick also occur below..... | 640 | 31q, 30w, 30x. <i>Lingulella isse</i> —31q. <i>Dikellocephalus?</i> sp.?—31q. In drift bowlders: <i>Eoorthis desmopleura</i> —30w. <i>Schizambon typicalis</i> —30w. <i>Agraulos</i> —30w. <i>Solenopleura</i> —30w. <i>Ilænurus</i> —30w. <i>Crepicephalus</i> —30x. <i>Ptychoparia</i> —30x. |
| 1b. Shaly dark-gray to bluish-gray arenaceous limestone, with small dark concretions in some layers..... | 90 | 34g. <i>Eoorthis desmopleura</i> —34g. |
| 1c. Gray siliceous limestone in layers of varying thickness, 4 inches to 2 feet, banded with dark cherty layers and purer arenaceous limestone. The chert takes the form of flattened nodules and very thin irregular layers..... | 340 | 33l. <i>Eoorthis desmopleura</i> —33l. <i>Solenopleura</i> —33l. <i>Ilænurus?</i> —33l. |
| 1d. Shaly and thin-bedded bluish gray arenaceous limestone..... | 65 | |
| 1e. Gray siliceous limestone in layers 2 inches to 2 feet thick. The lower part, where not metamorphosed, is dove-colored and in layers 6 inches to 3 feet thick, with some gray cherty matter in flattened nodules and thin layers that weather a dark brown..... | 355 | 30m. <i>Obolus tetonensis leda</i> —30m. Fragments of the free cheek of a trilobite—30m. |
| Total of Notch Peak limestone..... | 1,490 | |
| <i>Orr formation</i> [Walcott, 1908a, p. 10]: c | | |
| 1a. Bluish-gray to gray compact limestone in layers 1 inch to 2 feet thick. On weathering, the thicker layers break down into thin irregular layers which form a talus of angular fragments..... | 375 | Fragments of trilobites. |
| 1b. Sandy and siliceous bluish and drab-colored shales, with interbedded bands of dark bluish-gray limestone 6 inches to 2 feet thick..... | 84 | 30l, 30y. Section of erinoid column—30l. <i>Obolus rotundatus</i> —30y. <i>Lingulella isse</i> —30y. <i>Lingulella manticola</i> —30l. <i>Anomocare</i> —30l, 30y. <i>Ptychaspis</i> —30l. |
| | | 32f. <i>Lingulella manticola</i> —32f. <i>Lingulella perattenuata</i> —32f. <i>Lingulella pogonipensis</i> —32f. |

^a The line of separation between the Middle and Lower Cambrian occurs somewhere in the Brigham quartzite, and this thickness (5,420 feet) probably includes several hundred feet of Lower Cambrian beds.
^b Section exposed on the east and southeast slopes and ridges of Notch Peak.
^c The section is carried along the strike of the exposed strata 2 miles east to the west side of Orr Ridge, where the rocks of the Orr formation are unmetamorphosed.

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

Utah: House Range, Millard County—Continued.

| House Range section. [Walcott, 1908f, pp. 173-185.] | Localities and species in the House Range section. | Other localities and species in Utah and Nevada shown in their approximate strati- graphic position. |

a This section of beds which are doubtfully referred to the Langston was measured at the same locality as the shale forming 1h of the Howell formation, which is believed to be equivalent to the Spence shale member of the Ute limestone of northeastern Utah.

b Section exposed at the westward bend of Dome Canyon.

c Section exposed on the west slope and foothills of the House Range north and south of Dome Canyon.

Detailed stratigraphic distribution of Cambrian and Ordovician Brachiopoda—Continued.

Vermont.

The localities in Vermont are somewhat scattering, but most of them are confined to a fairly well-marked horizon in the Lower Cambrian. Two (319f and 227) occur in the Ordovician, four (28, 16n, 87', and 319q) in the Upper Cambrian, and two (28a and 319s) in the Middle Cambrian. The interrelations of these localities (see index for numbers) are obscure and stratigraphic comparisons would have little value.

Virginia and Maryland.

All but two of the localities in Maryland and Virginia (see index for numbers) occur in the same Lower Cambrian sandstone horizon. One Upper Cambrian locality (92b) and one Middle (47h) have been identified.

Wales.

See England, Scotland, and Wales, where the different horizons are more or less closely differentiated and correlated, with complete lists of localities and included species.

Wisconsin, Michigan, Minnesota, and Iowa.

Two localities (339 and 364a) from the Lower Ordovician Oneota dolomite and three (328b, 339a, and 364) from the Upper Cambrian St. Lawrence formation have been identified by Sardeson [1896, pp. 95 and 96]. The remainder are from the "St. Croix sandstone," and have all been referred to the Upper Cambrian, with the following exceptions: 79x, 83⁴, 84, 84f, 84s, 328e, 328g, 339e, 339i, 339j, and 339k. These eleven localities occur in the lower portion of the "St. Croix sandstone" and while they may belong in the Upper Cambrian, they have been placed in the Middle Cambrian because of the entire absence in the collections at our disposal of characteristic Upper Cambrian forms.

Wyoming.

See both South Dakota and Montana for general discussion of stratigraphy.

HABITAT.

The conditions in which the Cambrian brachiopods are found indicate that some of them were gregarious in habit, and that many persisted through marked changes of environment and sedimentation. *Micromitra (Iphidella) pannula*, for instance, is found in sandstone, siliceous and argillaceous shale, and limestone. It has a wide distribution in the Cordilleran province of western North America, and has a vertical range of 2,000 feet or more. Other forms, such as *Micromitra haydeni*, are known only from one locality and one layer of rock. A large number of species occur in sandstone and shales that are evidently of shallow-water origin; others occur in limestones that were probably deposited in relatively deep water. The evidence indicates that their habitat largely ranged from between tides to a depth of 1,000 to 2,000 feet. Some forms may have had a greater bathymetric range, but the evidence in favor of such a conclusion is not known to me.

In the following list there has been brought together a summary statement of the character of the sediment in which each of the genera taken up in this monograph occurs. Gradations from one type of sediment to another are so frequent and close that some of the separations may be considered arbitrary, though most of the determinations have been made by an examination of the hand specimen upon which the species is preserved. The numbers in the columns give the number of species occurring in the different classes of sediment and the number which have been identified from more than one class. The totals at the end of the table give the number of species and the number of genera, respectively, that have been identified from the different sediments.

It is probable that a reexamination of some of the specimens would justify their transfer to another column; for instance, the one sandstone representative of the genus *Huenella* might be found to occur in a calcareous sandstone or arenaceous limestone, which might equally as well be placed in the limestone column; but the table as a whole and the figures for each genus seem to indicate that the various genera are by no means confined to nor even characteristic of a given type of sediment. On the other hand, a similarly prepared table of the species in the monograph showed that with few exceptions each of the species is confined to one type of sediment. Disregarding those species (about 200) which have been found at but one locality, the table showed that out of over 500 specific occurrences only 150 had been identified from more than one type of sediment. Errors in the identification of sediment would be of more importance in the latter case than in that of the genera, but none of the specimens were reexamined and in none of the tables has there been any rearrangement of the figures.

List of genera and subgenera, alphabetically arranged, giving number of species occurring in the different types of sediment.

LOCALITIES.

The following list gives all known data concerning all localities from which fossils described in this paper have been obtained. After most of them reference is given to the pages on which their stratigraphic position is shown (pp. 124-159). Those that are without references are more or less isolated places for which stratigraphic data are lacking and which are without near neighbors to which they may be profitably compared. An asterisk (*) placed before the name of a species indicates that the place from which it is cited is its type locality. In localities 1-227 and C1-C75 the Brachiopoda are not accompanied by author names, but for purposes of identification the author names follow all other listed species. In localities 300 to 396z all the listed species are accompanied by a reference to either the place of citation or the museum in which the specimens are located. In all lists the Brachiopoda are placed first.

Numbers 1-227 were assigned to the different localities represented in the United States National Museum at the time of their accession and indicate distinct faunules. Numbers

C1-C75 (pp. 286-291) were assigned to the faunules collected by the expedition to China of the Carnegie Institution of Washington. Numbers 300-396z (pp. 229-286) have been arbitrarily assigned to localities mentioned in the literature or unnumbered localities in the United States National Museum collections, and the included species may not occur together as do those of the former localities. For each of the species listed in localities 300-396z it is simply true that the description of the locality under which it is placed gives all available information as to its stratigraphic and geographic position and the authority for so listing it.

Localities 1-227, U. S. National Museum.

1 (about 50 feet above 1a). (For stratigraphic position and association, see p. 140.) Middle Cambrian: Shales of zone A of No. 7 of the Manuels Brook section [Walcott, 1891b, p. 261], Manuels Brook, a small stream which flows into Conception Bay from the east, near Topsail Head, Newfoundland (C. D. Walcott, 1888).

| * <i>Obolus fragilis</i> . | <i>Conocoryphe matthewi</i> (Hartt). |
| <i>Lingulella ferruginea</i> . | <i>Paradoxides hicksi</i> Salter. |
| <i>Lingulella ferruginea?</i> | <i>Paradoxides</i> sp. |
| <i>Acrothele matthewi</i> . | <i>Anopolenus venustus</i> Billings. |
| <i>Acrotreta misera</i> . | <i>Erinnys venulosa</i> Salter. |

Walcott [1891b, p. 261] cites the following additional species:

| | |
|--------------------------------------|-------------------------------------|
| <i>Hyolithes</i> sp. a. | <i>Conocoryphe elegans</i> (Hartt). |
| <i>Agnostus</i> 3 sp. | <i>Agraulos socialis</i> Billings. |
| <i>Microdiscus punctatus</i> Salter. | <i>Liostracus tener</i> (Hartt). |

1a (=6n and 6l, about 50 feet below 1). (For stratigraphic position and association, see p. 140.) Middle Cambrian: Shales near the top of No. 6 of the Manuels Brook section [Walcott, 1891b, p. 261], Manuels Brook, Conception Bay, Newfoundland (C. D. Walcott, 1888).

| | |
|--------------------------------------|-------------------------------------|
| <i>Obolus fragilis</i> . | <i>Liostracus tener</i> (Hartt). |
| <i>Lingulella ferruginea</i> . | <i>Conocoryphe elegans</i> (Hartt). |
| <i>Acrothele matthewi</i> . | <i>Paradoxides davidis</i> Salter. |
| <i>Agraulos socialis</i> (Billings). | <i>Paradoxides</i> sp. |

11 (same horizon as 1v). (For stratigraphic position and association, see p. 138.) Lower Cambrian: Shales of No. 3 of the Silver Peak group, Barrel Spring section [Walcott, 1908f, p. 189^a], 2.5 miles (4 km.) south of Barrel Spring and 0.5 mile (0.8 km.) east of road, in the extreme southeastern corner of the Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (F. B. Weeks, 1899).

| | |
|-----------------------------|---------------------------------|
| <i>Acrothele spurri?</i> | <i>Ptychoparia</i> sp. |
| <i>Acrotreta claytoni</i> . | <i>Olenellus gilberti</i> Meek. |

1m (=1p). (For stratigraphic position and association, see p. 138.) Lower Cambrian: Limestones of No. 2 of the Silver Peak group, Barrel Spring section [Walcott, 1908f, p. 189], about 2.5 miles (4 km.) south of Barrel Spring and 0.5 mile (0.8 km.) east of the road, in the extreme southeastern corner of the Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (F. B. Weeks, 1899).

| | |
|--------------------------------------------------------------|---------------------------------|
| <i>Micromitra</i> (<i>Paterina</i>) <i>prospectensis</i> . | <i>Olenellus gilberti</i> Meek. |
| <i>Nisusia</i> (<i>Jamesella</i>) <i>argenta</i> . | |

1p (=1m, which see). (For stratigraphic position and association, see p. 138.) (F. B. Weeks, 1899.)

| | |

| * <i>Kutorgina perugata</i> . | <i>Ptychoparia</i> sp. |
| * <i>Siphonotreta?</i> <i>dubia</i> . | <i>Wanneria gracile</i> Walcott. |
| * <i>Swantonina weeksi</i> . | <i>Olenellus argentus</i> Walcott. |

2. (For stratigraphic position and association, see p. 140.) Middle Cambrian: Shales of zone B of No. 7 of the Manuels Brook section [Walcott, 1891b, p. 261], Manuels Brook, Conception Bay, Newfoundland (C. D. Walcott, 1888).

| | |
|--------------------------------|-----------------------------|
| <i>Obolus fragilis</i> . | <i>Acrothele matthewi</i> . |
| <i>Lingulella ferruginea</i> . | |

^a The species mentioned by Walcott [1908f, p. 189] occur at slightly different localities (11 and 1v), none of the species being common to both localities.

Walcott [1891b, p. 261] cites the following:

Linnarssonia misera=Acrotreta misera.
 Orthis sp.
 Stenotheca sp.
 Agnostus punctuosus Angelin.
 Agnostus 5 sp.
 Microdiscus punctatus Salter.
 Paradoxides davidis Salter.
 Paradoxides hicksi Salter.
 Paradoxides sp.

Anopolenus venustus Billings.
 Conocoryphe elegans (Hartt).
 Ctenocephalus matthewi (Hartt).
 Erinnys venulosa Salter.
 Ptychoparia robbi Hartt.
 Ptychoparia variolaris Salter.
 Holocephalina inflata Hicks.
 Agraulos socialis Billings.

2a (same horizon as 1). (For stratigraphic position and association, see p. 140.) Middle Cambrian: Above and to the north of the limestone, in the shales of the *Paradoxides* zone, Topsail Head, Conception Bay, Newfoundland (C. D. Walcott, 1888).

Lingulella ferruginea.

2b. Lower Cambrian: Limestone just north of Beman Park, in the northeastern part of the city of Troy, Troy quadrangle (U. S. G. S.), Rensselaer County, N. Y. (H. E. Dickhaut, 1899).

Micromitra (*Paterina*) *labradorica*.

Bicia gemma.

**Bicia whiteavesi*.

Obolella crassa.
Botsfordia cæolata.
Billingsella salemensis.

2d. Lower Cambrian: Arenaceous limestone in the knobs just east of Beman Park and southwest of Brunswick, near Troy, Troy quadrangle (U. S. G. S.), Rensselaer County, N. Y. (H. E. Dickhaut, 1899).

Obolella crassa.

2e (see 3b). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Shale 25 feet (7.6 m.) above the basal quartzite, Seeley Street, St. John, St. John County, New Brunswick (S. W. Loper, 1899).

Protorthis billingsi.

2f (3 feet below 2g; see 308e). (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstones of Division 1b1 of Matthew's [1895a, p. 108] *Protolenus* zone, Hanford Brook, St. John County, New Brunswick (C. D. Walcott and S. W. Loper, 1899).

**Lingulella martinensis*.

Acrothele prima.

**Acrotreta inflata*.
Acrotreta sagittalis transversa.

2g (3 feet above 2f and underlying 2h; see 308e). (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstones of Division 1b1 of Matthew's [1895a, p. 108] *Protolenus* zone, Hanford Brook, St. John County, New Brunswick (C. D. Walcott and S. W. Loper, 1899).

Lingulella martinensis.

**Acrotreta inflata*.

Acrotreta sagittalis.
Acrotreta sagittalis transversa.

Matthew cites the following additional species from Division 1b1:

Acrothele matthewi? (Hartt).

**Acrothele matthewi prima* Matthew=*Acrothele prima*.

**Hipponicharion eos* Matthew.
Beyrichona tinea planata (Matthew).

2h (overlying 2g; see 301). (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstones of Division 1b2 of Matthew's [1895a, p. 108] *Protolenus* zone, Hanford Brook, St. John County, New Brunswick (C. D. Walcott and S. W. Loper, 1899).

Lingulella martinensis.

Trematobolus pristinus.

Acrothele prima.

**Acrothele prima costata*.
Acrotreta sagittalis transversa.

Matthew cites the following additional species from Division 1b2:

Beyrichona tinea Matthew.

**Beyrichona tinea planata* (Matthew).

Beyrichona rotundata Matthew.

Beyrichona ovata Matthew.
Indiana secunda Matthew.

2i (underlying 2k). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstones of Division 1b3 of Matthew's [1895a, p. 108] *Protolenus* zone, Hanford Brook, St. John County, New Brunswick (C. D. Walcott and S. W. Loper, 1899).

Lingulella ferruginea?

Lingulella martinensis.

Botsfordia sp.

Trematobolus pristinus.

Acrothele prima.
Acrothele prima costata.
Acrotreta sagittalis magna.
Acrotreta sagittalis transversa.

Matthew cites the following additional species from Division 1b3:

| | |
|---------------------------------------|-------------------------------------------|
| Bradoria benepuncta (Matthew). | Beyrichona tinea Matthew. |
| Bradoria minor (Matthew). | Beyrichona tinea planata (Matthew). |
| *Bradoria cambrica (Matthew). | *Beyrichona tinea triangularis (Matthew). |
| Bradoria oculata (Matthew). | Beyrichona papilio (Matthew). |
| Indiana lippa (Matthew). | *Beyrichona rotundata Matthew. |
| Indiana secunda pyriformis (Matthew). | *Hipponicharion minus Matthew. |
| Walcottella fusiformis (Matthew). | *Hipponicharion cavatum Matthew. |

2k (just above 2i). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstones of Division 1b3 of Matthew's [1895a, p. 108] *Protolenus* zone, Hanford Brook, St. John County, New Brunswick (C. D. Walcott and S. W. Loper, 1899).

Trematoholus pristinus.
Acrothele prima costata.
Acrotreta sagittalis transversa.

Matthew cites the following additional species from this locality:

Indiana secunda pyriformis (Matthew).
Beyrichona tinea Matthew.

2l (underlying 2m). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Limestone at the base of the *Paradoxides* zone [Matthew, 1895a, p. 108], Hanford Brook, St. John County, New Brunswick (S. W. Loper, 1899).

| | |
|----------------------------------|-----------------------------|
| Lingulella ferruginea. | Acrotreta sagittalis magna. |
| Acrothele matthewi. | Protorthis billingsi. |
| Acrothele matthewi multicostata. | *Eoorthis hastingsensis. |

Matthew cites the following additional species from the base of the *Paradoxides* zone at this locality:

Beyrichona tinea Matthew.

2m (overlying 2l). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Shales near the base of the *Paradoxides* zone [Matthew, 1895a, p. 108], Hanford Brook, St. John County, New Brunswick (S. W. Loper, 1899).

| | |
|------------------------|-------------------------|
| Lingulella ferruginea. | Protorthis billingsi. |
| Acrothele matthewi. | Eoorthis hastingsensis. |

2n. Lower Cambrian: Limestone boulders in conglomerate along the shore of the St. Lawrence, near Trois Pistoles, Temiscouata County, Quebec, Canada (C. D. Walcott, 1899).

*Micromitra (Paterina) bella.
*Micromitra (Paterina) logani.

2o (see 2p and 2r). Lower Cambrian: Limestone boulders in conglomerate on shore at east entrance to harbor at Bic, Rimouski County, Quebec, Canada (C. D. Walcott, 1899).

| | |
|------------------------------------|--------------------|
| Micromitra (Paterina) bella. | Botsfordia cælata. |
| Micromitra (Paterina) labradorica. | Yorkia wanneri?. |
| Bicia gemma. | Nisusia festinata. |
| Kutorgina cingulata. | Discinella sp. |
| Obolella crassa. | |

2p (see 2o and 2r). Lower Cambrian: Limestone on south side of the road a little west of Bic and half a mile (0.8 km.) west of the road leading to the wharf, Rimouski County, Quebec, Canada (C. D. Walcott, 1899).

Bicia gemma.
Botsfordia cælata.

2r (see 2o and 2p). Lower Cambrian: Limestone boulders in a conglomerate in a cut on the Intercolonial Railway, 2 miles (3.2 km.) west of Bic railway station, Rimouski County, Quebec, Canada (C. D. Walcott, 1899).

| | |
|-------------------------------------|----------------------------|
| *Micromitra nesus. | Botsfordia cælata. |
| Micromitra (Paterina) labradorica?. | Callavia bicensis Walcott. |

2s (see 2t). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Limestone in upper part of *Paradoxides* zone, at Hastings Cove [see Matthew, 1898b, p. 38], on Kennebecasis Bay, 0.5 mile (0.8 km.) northeast of Torryburn, on the Intercolonial Railway, northeast of St. John, St. John County, New Brunswick (C. D. Walcott, 1899).

| | |
|----------------------------------|------------------------------|
| Lingulella ferruginea. | Acrotreta sagittalis. |
| Acrothele matthewi. | *Acrotreta sagittalis magna. |
| Acrothele matthewi multicostata. | Billingsella coloradoensis. |
| *Acrotreta gracia. | Billingsella sp. |
| Acrotreta misera. | Eoorthis hastingsensis. |

Matthew cites the following additional species from this locality:

Indiana primæva (Matthew).

Indiana dermatoides (Walcott).

2t (shale in which limestone of 2s is interbedded). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Shales in upper part of *Paradoxides* zone, at Hastings Cove [see Matthew, 1898b, p. 38], on Kennebecasis Bay, 0.5 mile (0.8 km.) northeast of Torryburn, on the Intercolonial Railway, northeast of St. John, St. John County, New Brunswick (C. D. Walcott, 1899).

**Acrothele matthewi multicostata*.

Acrotreta misera.

2u (below 2x; see 308g). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Lowes beds exposed on the south side of Long Island, Kennebecasis Bay [see Matthew, 1898a, pp. 124 and 127], St. John County, New Brunswick (C. D. Walcott, 1899).

Trematobolus kempianum.

**Protorthis helena*.

Protorthis (*Loperia*) *dugaldensis*.

2x (=locality given by Matthew [1892, p. 59]; a higher horizon than 2u). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Thin-bedded sandstones of Division 2 of Matthew [1892, p. 59], on the south shore of Long Island, Kennebecasis Bay [see Matthew, 1898a, pp. 124 and 127], St. John County New Brunswick (C. D. Walcott, 1899).

**Lingulella minor*.

Lingulella minor?

Lingulella (*Lingulepis*) *starri*.

2y. (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstone about 25 feet (7.6 m.) above the Lower Cambrian, on the southeast side of Catons Island, in Long Reach, St. John River, Kings County, New Brunswick (C. D. Walcott, 1899).

Botsfordia pulchra.

2z. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Nolichucky(?) shale [Campbell, 1899, p. 3], near Shipley Ferry, 0.75 mile (1.2 km.) northwest of Bethany Chapel, northeastern corner of the Roan Mountain quadrangle (U. S. G. S.), Sullivan County, Tenn. (M. R. Campbell, 1894).

Dicellomus appalachia.

2z'. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales in the Honaker limestone [Campbell, 1899, p. 3], at Wallace switch, about 5 miles (8 km.) northeast of Bristol, Bristol quadrangle (U. S. G. S.), Sullivan County, Tenn. (T. C. Mendenhall and M. R. Campbell, 1894).

Dicellomus appalachia.

3 (highest horizon on Manuels Brook). (For stratigraphic position and association, see p. 140.) Upper Cambrian: Shaly limestones 300 feet (91.4 m.) above the *Paradoxides* zone, Manuels Brook, Conception Bay, Newfoundland (C. D. Walcott, 1888).

Lingulella ferruginea.

Acrothele matthewi.

| *Acrotreta sagittalis transversa*.

| *Orusia lenticularis*.

3a. Lower Cambrian: 450 feet (137.1 m.) below the quartzite in the St. John formation and over 500 feet (152.4 m.) below the *Protolenus* fauna of Matthew [see Walcott, 1900, pp. 320-322], Hanford Brook, St. John County, New Brunswick (C. D. Walcott, 1899).

Micromitra (*Paterina*) *labradorica*.

3b (see 2e). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Shale at the base of the *Paradoxides* zone, head of Seeley Street, St. John, St. John County, New Brunswick (S. W. Loper, 1899).

Acrothele matthewi.

Protorthis billingsi.

Protorthis quacoensis.

3c. (For stratigraphic position and association, see p. 158.) Middle Cambrian: Shales about 75 feet (22.9 m.) above the quartzitic sandstones of the Cambrian, at Ophir, Oquirrh Range, Tooele County, Utah (H. E. Dickhaut, 1900).

Obolus (*Westonia*) *ella*.

3d. (For stratigraphic position and association, see p. 157.) Middle Cambrian: Concretionary limestone about 100 feet (30.5 m.) above the quartzitic sandstones of the Cambrian, at Ophir, Oquirrh Range, Tooele County, Utah (H. E. Dickhaut, 1900).

Micromitra sp.

Micromitra (*Paterina*) *labradorica utahensis*.

| *Obolus* (*Westonia*) *ella*.

| *Olenoides?*

- 3e. (For stratigraphic position and association, see p. 156.) Middle Cambrian: Thin-bedded limestone less than 400 feet (121.9 m.) above the quartzitic sandstones of the Cambrian, at Ophir, Oquirrh Range, Tooele County, Utah (H. E. Dickhaut, 1900).

Micromitra sp.

*Micromitra (Iphidella) pannula ophirensis.

Obolus matinalis.

Obolus tetonensis.

Lingulella arguta.

*Acrothele subsidua laevis.

*Acrotreta ophirensis.

*Acrotreta ophirensis rugosa.

Olenoides?.

- 3g (see 360h). Middle Cambrian: Shales on river bank 250 feet (76.2 m.) above west end of Denver and Rio Grande Railway tunnel, Glenwood Springs, Garfield County, Colo.

Obolus (Westonia) ella.

Lingulella sp.

- 3h. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale and shaly limestone, on McNeil Brook, 1.5 miles (2.4 km.) east of Marion Bridge, Cape Breton, Nova Scotia (S. W. Loper, 1900).

*Obolus acadicus.

Obolus (Bröggeria) salteri.

Lingulella concinna.

Lingulella ferruginea.

Schizambon priscus.

- 3i. (For stratigraphic position and association, see p. 132.) Middle Cambrian: Compact, fine-grained, thin-bedded gray sandstone of the *Paradoxides* zone, on McLean Brook, 1 mile (1.6 km.) east of McCodrum Brook and 1.5 miles (2.4 km.) west of Marion Bridge, Cape Breton, Nova Scotia (S. W. Loper, 1900). Matthew [1903, p. 195] says the horizon is his Division C2b.

*Lingulella cania.

Lingulella concinna.

Lingulella ferruginea.

Lingulella rotunda.

*Lingulella (Lingulepis) exigua.

Acrothyra proavia.

- 3j (same locality as 5j, but 25 feet above; see 4v and 4q). Middle Cambrian: Above the quartzitic sandstones, in a shale corresponding in position to the upper part of shale No. 6 of the Dearborn River section [Walcott, 1908f, p. 202], about 6 miles (9.6 km.) west-northwest of Scapegoat Mountain, on the Continental Divide between Bar Creek and the headwaters of the south fork of the North Fork of Sun River, Coopers Lake quadrangle (U. S. G. S.) Powell County, Mont. (C. D. Walcott, 1905).

Obolus mcconnelli.

Bathyriscus productus (Hall and Whitfield).

- 3n. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Thin-bedded sandstone on Salmon River, Gillis Hill, 13 miles (20.9 km.) south of Marion Bridge, eastern Cape Breton, Nova Scotia (S. W. Loper, 1900).

Lingulella minor.

Lingulella (Lingulepis) exigua.

*Acrotreta convexa.

- 3o (see 372c). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales in the first ravine south of the post office at Barachois, east of Little Bras d'Or Lake, eastern Cape Breton, Nova Scotia (S. W. Loper, 1900).

Lingulella concinna.

- 3p. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales in ravine 0.5 mile (0.8 km.) north of McMullins, on the crossroad to Boisdale station, eastern Cape Breton, Nova Scotia (S. W. Loper, 1900).

Lingulella concinna.

- 3q. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale in Barachois Glen, 4 miles (6.4 km.) south of Little Bras d'Or Lake, eastern Cape Breton, Nova Scotia (S. W. Loper, 1900).

Obolus (Bröggeria) salteri.

Lingulella concinna.

Schizambon priscus.

Acrotreta bisecta.

- 3s (same horizon as 1z, 4, and 15b; =3t and 8g). (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 1,700 feet (518.2 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian, in the shaly limestones and calcareous shales of the Wheeler formation [Walcott, 1908f, p. 181], in the eastern part of Wheeler Amphitheater, east of Antelope Springs, House Range [Walcott, 1908f, Pls. XIII and XV], Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1903 and 1905).

Obolus mcconnelli pelias.

Acrothele subsidua.

Acrotreta attenuata.

Agnostus bidens (Meek).

Ptychoparia kingi (Meek).

Ptychoparia sp.

Asaphiscus wheeleri (Meek).

- 3t** (=3s, which see). (For stratigraphic position and association, see p. 156.)
- 3v.** (For stratigraphic position and association, see p. 158.) Middle Cambrian: About 200 feet (61 m.) above the Lower Cambrian in the "Spence shale" [Walcott, 1908f, p. 183] (described in this monograph, p. 158, as 1h of the Howell formation), in Dome Canyon, about 5 miles (8 km.) west of Antelope Springs, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.
(See p. 158 for list of species.)
- 3w** (same horizon as 30g and 11q). (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 2,350 feet (716.3 m.) above the Lower Cambrian and 2,050 feet (624.8 m.) below the Upper Cambrian, in the central portion of the thin-bedded limestones forming 1c of the Marjum limestone [Walcott, 1908f, p. 180], in the cliff about 2 miles (3.2 km.) southeast of Marjum Pass, House Range [see Walcott, 1908f, Pls. XIII and XV], Millard County, Utah (C. D. Walcott, 1903).
- Lingulella arguta. | Ptychoparia.
Acrotreta bellatula. | Neolenus.
- 3x** (=11x). (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 2,200 feet (670.6 m.) above the Lower Cambrian and 2,200 feet (670.6 m.) below the Upper Cambrian, in the limestones forming 1d of the Marjum limestone [Walcott, 1908f, p. 180], 2.5 miles (4 km.) east of Antelope Springs, in ridge east of Wheeler Amphitheater, House Range [Walcott, 1908f, Pls. XIII and XV], Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).
- Micromitra sculptilis. | Eoorthis remnicha?.
Micromitra (Iphidella) pannula ophirensis | *Eoorthis thylene.
Obolus mcconnelli pelias. | *Syntrophia? unxia.
Obolus rotundatus. | Agnostus 3 sp.
Lingulella arguta. | Ptychoparia.
Acrothele subsidua. | Neolenus inflatus Walcott.
Acrothele subsidua laevis. | Neolenus intermedius Walcott.
Acrotreta attenuata. | Neolenus superbus Walcott.
Acrotreta ophirensis. | Ogygopsis?.
- 3y.** (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 2,150 feet (655.3 m.) above the Lower Cambrian and 2,250 (685.8 m.) below the Upper Cambrian, in the shaly limestones forming 1d of the Marjum limestone [Walcott, 1908f, p. 180], 2.5 miles (4 km.) east of Antelope Springs, in ridge east of Wheeler Amphitheater, House Range [Walcott, 1908f, Pls. XIII and XV], Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).
- Obolus mcconnelli pelias. | Ptychoparia.
Acrotreta ophirensis. | Ogygopsis?.
- 4** (same horizon as 3s). (For stratigraphic position and association, see p. 156.) Middle Cambrian: Drift pieces believed to have come from the Wheeler formation [Walcott, 1908f, p. 181], collected near Antelope Springs, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (J. F. Gibbs, 1839).
- *Acrothele subsidua. | Ptychoparia kingi (Meek).
Agnostus interstrictus White. | Asaphiscus wheeleri (Meek).
- 4e** (see 4m and 4n). Middle Cambrian: Limestones about 950 feet (289.6 m.) above the unconformable base of the Cambrian, in the divide at head of Jackson Creek (locally known as Sheep Creek), a creek flowing into Jackson Lake about 0.5 mile (0.8 km.) south of its northwestern corner, Teton Mountains, Grand Teton quadrangle (U. S. G. S.), Uinta County, Wyo. (C. D. Walcott, 1898).
- *Obolus tetonensis. | *Acrotreta microscopica tetonensis.
Lingulella (Lingulepis) acuminata meeki. | Billingsella coloradoensis.
(Possibly the last named is from a bed different from that containing the other species.)
- 4g** (50 feet below 4h; see 4h, 4k, and 4p). Middle Cambrian: About 325 feet (99.1 m.) above the base of the Cambrian, in the Flathead shales of Peale [1893, p. 21], 1 mile (1.6 km.) north of the junction of East Gallatin and West Gallatin (Gallatin) rivers, 4 miles (6.4 km.) east-northeast of Logan, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (C. D. Walcott).
- Obolus (Westonia) ella.
- 4h** (50 feet above 4g; see 4g, 4k, and 4p). Middle Cambrian: About 375 feet (114.3 m.) above the base of the Cambrian, in limestone interbedded in the Flathead shales of Peale [1893, p. 21], 1 mile (1.6 km.) north of the junction of East Gallatin and West Gallatin (Gallatin) rivers, 4 miles (6.4 km.) east-northeast of Logan, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (C. D. Walcott).
- Micromitra pealei. | Lingulella (Lingulepis) acuminata meeki.
Obolus tetonensis. | Acrotreta pyxidicula.

- 4j. Middle Cambrian: Limestone at the head of Deep Creek; Canyon quadrangle (U. S. G. S.), Yellowstone National Park, Wyo.

Billingsella plicatella.

Eoorthis sp.

**Huenella abnormis*.

The first and third of these fossils may not have been collected from the same bed.

- 4k (4i is limestone interbedded in these shales; see 4g, 4h, and 4p). Middle Cambrian: About 725 feet (221 m.) above the base of the Cambrian, in the shales of the Gallatin formation of Peale [1893, Pl. IV], on the north side of West Gallatin (Gallatin) River, northeast of Logan, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (C. D. Walcott, 1898).

Obolus (*Westonia*) *ella*.

- 4l. (For stratigraphic position and association, see pp. 140 and 158.) Lower Cambrian: Limestone in the equivalent of the Pioche formation at Pioche and in the House Range [Walcott, 1908a, p. 11], on a ridge 2.5 miles (4 km.) northwest of the town of Cherry Creek, White Pine County, Nev. (O. H. Hershey).

Micromitra (*Iphidella*) *pannula*.

Acrotreta claytoni.

Acrotreta primæva.

- 4m (about 175 feet below 4n). Middle Cambrian: Sandstones about 150 feet (45.7 m.) above the unconformable base of the Cambrian, in the divide at the head of Jackson Creek (locally known as Sheep Creek), a creek flowing into Jackson Lake about 0.5 mile (0.8 km.) south of its northwestern corner, Teton Mountains, Grand Teton quadrangle (U. S. G. S.), Uinta County, Wyo. (C. D. Walcott, 1898).

Obolus tetonensis.

- 4n (about 175 feet above 4m). Middle Cambrian: Limestone about 325 feet (99.1 m.) above the unconformable base of the Cambrian, in divide at the head of Jackson Creek (locally known as Sheep Creek), a creek flowing into Jackson Lake about 0.5 mile (0.8 km.) south of its northwestern corner, Teton Mountains, Grand Teton quadrangle (U. S. G. S.), Uinta County, Wyo. (C. D. Walcott and F. B. Weeks, 1898).

Micromitra pealei.

Obolus (*Westonia*) *ella*.

Lingulella helena.

Acrotreta attenuata.

M. pealei also occurs in locality 4n', which is probably a slightly different bed at the locality given for 4n.

- 4o (about 50 feet above 4n). Middle Cambrian: Shale about 375 feet (115 m.) above the unconformable base of the Cambrian, in divide at the head of Jackson Creek (locally known as Sheep Creek), a creek flowing into Jackson Lake about 0.5 mile (0.8 km.) south of its northwestern corner, Teton Mountains, Grand Teton quadrangle (U. S. G. S.), Uinta County, Wyo. (C. D. Walcott, 1898).

Acrotreta definita.

- 4p (see 4g, 4h, and 4k). Middle Cambrian: About 225 feet (68.6 m.) above the base of the Cambrian, in limestones interbedded in the Flathead shales of Peale [1893, p. 21], on the north side of West Gallatin (Gallatin) River, 2 miles (3.2 km.) northeast of Logan, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (C. D. Walcott, 1898).

Micromitra pealei.

- 4q (115 feet above 4v; see 3j and 4v). Middle Cambrian: About 315 feet (96 m.) above the unconformable base of the Cambrian and 190 feet (57.9 m.) above the top of the quartzitic sandstones, in a shale which corresponds in position to the upper part of shale No. 6 of the Dearborn River section [see Walcott, 1908f, p. 202], on the ridge between Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. G. S.), Powell County, Mont. (C. D. Walcott, 1905).

**Micromitra* (*Iphidella*) *nyssa*.

Micromitra (*Iphidella*) *pannula*.

**Acrothele colleni*.

Wimanella simplex.

Ptychoparia 3 sp.

Bathyuriscus productus (Hall and Whitfield).

Zacanthoides.

- 4q' (just below 4q; see 3j, 4q, and 4v). Middle Cambrian: Limestone about 310 feet (94.5 m.) above the unconformable base of the Cambrian and 185 feet (56.4 m.) above the top of the quartzitic sandstones, in a shale which corresponds in position to the upper part of shale No. 6 of the Dearborn River section [see Walcott, 1908f, p. 202], on the ridge between Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. G. S.), Powell County, Mont. (C. D. Walcott, 1905).

Micromitra (*Iphidella*) *pannula*.

Obolus (*Westonia*) *ella*.

- 4r. Upper Cambrian: Just above the Middle Cambrian, in the limestones of the Gallatin formation of Peale [1893, Pl. IV], on a ridge 8 miles (12.8 km.) east of Yellowstone River and 3 miles (4.8 km.) north-northeast of Mount Delano, Livingston quadrangle (U. S. G. S.), Park County, Mont. (C. D. Walcott, 1898).

Eoorthis remnicha.

4u. Middle Cambrian: Shales in the Gallatin formation of Peale [1893, Pl. IV], northwest side of canyon, 0.5 mile (0.8 km.) south of Helena, Jefferson County, Mont. (L. S. Griswold and C. D. Walcott, 1898).
Obolus (*Westonia*) *ella*.
Lingulella helena.

4v (115 feet below 4q; same horizon as 5j; see 3j and 4q). Lower Cambrian: About 200 feet (61 m.) above the unconformable base of the Cambrian and 75 feet (22.9 m.) above the top of the quartzitic sandstones, in a shale which corresponds in stratigraphic position to shale No. 6 of the Dearborn River section [see Walcott, 1908f, p. 202], Gordon Creek, 6 miles (9.6 km.) from South Fork of Flathead River, Ovando quadrangle (U. S. G. S.), Powell County, Mont. (C. D. Walcott, 1905).

Micromitra (*Iphidella*) *pannula*.

Obolus (*Westonia*) *ella*.

Acrothele colleni.

**Acrothele panderi*.

**Wimanella simplex*

Ptychoparia sp.

Olenopsis? sp.

Albertella helena Walcott.

Bathyuriscus productus (Hall and Whitfield)?

Bathyuriscus? sp.

4w (same horizon as 4q). Lower Cambrian: About 315 feet (96 m.) above the unconformable base of the Cambrian and 190 feet (57.9 m.) above the top of the quartzitic sandstones, in a shale which corresponds in position to shale No. 6 of the Dearborn River section [see Walcott, 1908f, p. 202], on Youngs Creek, about 5 miles (8 km.) from its junction with Danaher Creek, Ovando quadrangle (U. S. G. S.), Powell County, Mont. (C. D. Walcott, 1905).

Wimanella simplex.

Ptychoparia sp.

Zacanthoides sp.

4x (a little higher than 5f; see 4g, 4h, 4k, and 5f). Middle Cambrian: Limestone interbedded in the Wolsey shale [Weed, 1900, p. 285], at the base of a butte in Belt Park, about 6 miles (9.6 km.) northwest of Neihart, Little Belt Mountains quadrangle (U. S. G. S.), Cascade County, Mont. (C. D. Walcott, 1898).

Micromitra pealei.

Obolus tetonensis.

Scenella.

4y (= 54t, which see). (For stratigraphic position and association, see p. 149.) (C. D. Walcott, 1898.)
Obolus (*Westonia*) *ella*.
Billingsella coloradoensis.

5. Middle Cambrian: Siliceous shale on Hayward Creek, Braintree, Dedham quadrangle (U. S. G. S.), Norfolk County, Mass. (W. P. Rust, 1891).

Acrothele gamagei.

Hyalithes shaleri Walcott.

Agraulos quadrangularis (Whitfield).

Paradoxides harlani Green.

Grabau [1900] cites the following additional species from this locality:

Fucoids or trails?.

Parmophorella acadica (Hartt).

Hyalithes? *haywardensis* Grabau.

Ptychoparia rogersi Walcott.

5a (= 54t, which see). (For stratigraphic position and association, see p. 149.) (C. D. Walcott, 1898.)
Obolus wortheni.
Lingulella desiderata.
Billingsella coloradoensis.

5b (= 54s, which see). (For stratigraphic position and association, see p. 152.) (C. D. Walcott, 1893.)
 For the species occurring at this locality, see Locality 54s.

5c (= 54t, which see). (For stratigraphic position and association, see p. 149.) (C. D. Walcott and L. D. Burling, 1906.)
Obolus wortheni.
 **Acrotreta idahoensis*.
Billingsella coloradoensis.

5f (a little lower than 4x). Middle Cambrian: Limestone interbedded in the Wolsey shale [Weed, 1900, p. 285], in Meagher County, on the road to Wolsey, about 4 miles (6.4 km.) south of the divide at the head of Sawmill Creek and 11 miles (17.7 km.) south of Neihart, Little Belt Mountains quadrangle (U. S. G. S.), Cascade County, Mont. (C. D. Walcott, 1898).

Micromitra pealei.

Obolus (*Westonia*) *ella*.

Lingulella desiderata.

Scenella.

Dorypyge? *quadriceps* (Hall and Whitfield).

5h (=55d, which see). (For stratigraphic position and association, see p. 150.) (C. D. Walcott, 1898.)
Obolus (*Westonia*) *ella*.

5j (same horizon as 4v; same locality as 3j but 25 feet below). Lower Cambrian: Above the quartzitic sandstones, in a shale which corresponds in position to shale No. 6 of the Dearborn River section [see Walcott, 1908f, p. 202], about 6 miles (9.6 km.) west-northwest of Scapegoat Mountain, on the Continental Divide between Bar Creek and the headwaters of the south fork of North Fork of Sun River, Coopers Lake quadrangle (U. S. G. S.), Powell County, Mont. (C. D. Walcott, 1905).

Acrothele panderi.

Albertella helena Walcott.

5k. Middle Cambrian: Limestone in Meagher County, on the road to Wolsey, about 1 mile (1.6 km.) south of the divide at the head of Sawmill Creek and 8 miles (12.8 km.) south of Neihart, Little Belt Mountains quadrangle (U. S. G. S.), Cascade County, Mont. (C. D. Walcott, W. H. Weed, and F. B. Weeks, 1895).

Micromitra sp.

Dicellomus politus.

| **Schuchertina cambria*.

| *Billingsella coloradoensis*.

5l (50 feet below 5n at same locality; same horizon as 5p and 4l). (For stratigraphic position and association, see p. 141.) Lower Cambrian: Limestone on Smith Point, in Smith Sound, Trinity Bay, Newfoundland (C. D. Walcott, 1899).

Micromitra (*Paterina*) *labradorica*.

Olenellus?

5n (50 feet above 5l at same locality; 275 feet below 5o). (For stratigraphic position and association, see p. 141.) Lower Cambrian: Shale on Smith Point, in Smith Sound, Trinity Bay, Newfoundland (C. D. Walcott, 1899).

Obolella atlantica.

Callavia bröggeri (Walcott).

5o (about 275 feet above 5n; see 5l and 5n). (For stratigraphic position and association, see p. 141.) Lower Cambrian: Just below the Middle Cambrian, in shales on Smith Point, in Smith Sound, Trinity Bay, Newfoundland (S. W. Loper and C. D. Walcott, 1899).

Obolella atlantica.

Olenellus?

5p (same horizon as 5l and 4l). (For stratigraphic position and association, see p. 141.) Lower Cambrian: Limestone 300 feet (91.4 m.) southeast of the railway station, Manuels, Conception Bay, Newfoundland (C. D. Walcott, 1899).

Obolella atlantica.

Callavia bröggeri (Walcott).

5r. (For stratigraphic position and association, see p. 141.) Lower Cambrian: Limestone near the railroad track, 1.5 miles (2.4 km.) west of the railway station at Manuels, Conception Bay, Newfoundland (C. D. Walcott, 1899).

Micromitra (*Paterina*) *labradorica*.

Callavia bröggeri (Walcott).

5t. (For stratigraphic position and association, see p. 141.) Lower Cambrian: Shale and limestone nodules about 20 feet (6 m.) above the base of the Cambrian, on Redrock Point, near Chapple Cove, Hollywood Point, Conception Bay, Newfoundland (J. P. Howley and C. D. Walcott, 1899).

Micromitra (*Paterina*) *labradorica*.

Obolella atlantica.

Callavia bröggeri (Walcott).

6g. (For stratigraphic position and association, see p. 141.) Middle Cambrian: Limestone near the base of the Middle Cambrian, the lowest horizon carrying *Paradoxides*, northwest side of Chapple Arm Harbor, about 1 mile (1.6 km.) from its head, Trinity Bay, Newfoundland (J. P. Howley and C. D. Walcott, 1899).

Micromitra (*Iphidella*) *ornatella*.

Micromitra (*Iphidella*) *pannula maladensis*.

Lingulella ferruginea.

| *Acrothele matthewi*.

| *Acrotreta misera*.

| *Acrotreta sagittalis*.

6h. (For stratigraphic position and association, see p. 140.) Middle Cambrian: Limestone in the southwest cove of Chapple Arm, Trinity Bay, Newfoundland (C. D. Walcott, 1899).

Acrotreta misera.

6i (280 feet below 6s). (For stratigraphic position and association, see p. 140.) Middle Cambrian: Limestone about 300 feet (91.4 m.) below the base of the Upper Cambrian, on shore north of Fosters Point, Random Island, Random Sound, Newfoundland (C. D. Walcott, 1899).

Acrotreta sagittalis.

Agnostus.

Microdiscus.

6l (=1a, except that the fossils were collected on the east side of the brook). (For stratigraphic position and association, see p. 140.) (C. D. Walcott, 1899.)

Lingulella ferruginea.

Acrothele matthewi.

| *Acrotreta*?

| **Eoorthis papias*.

6n (=1a, except that the fossils were collected on the west side of the brook). (For stratigraphic position and association, see p. 140.) (C. D. Walcott, 1899.)

Lingulella ferruginea.

Acrothele matthewi.

Acrothele prima costata.

6r. (For stratigraphic position and association, see p. 140.) Middle Cambrian: Limestone on the west side of Manuels Brook, Conception Bay, Newfoundland (C. D. Walcott, 1899).

Lingulella ferruginea.

Acrotreta misera.

6s (=6u; 280 feet above 6i). (For stratigraphic position and association, see p. 140.) Upper Cambrian: Just north of Fosters Point, Random Island, Random Sound, Newfoundland (C. D. Walcott, 1899).

Lingulella ferruginea?

6u (same horizon as 6s). (For stratigraphic position and association, see p. 140.) Upper Cambrian: Shale on the west side of Manuels Brook, Conception Bay, Newfoundland (C. D. Walcott, 1899).

Lingulella ferruginea.

6v (375 feet above 6n). (For stratigraphic position and association, see p. 140.) Upper Cambrian: Shaly limestones 325 feet (99.1 m.) above the Middle Cambrian, Manuels Brook, Conception Bay, Newfoundland (C. D. Walcott, 1899).

Orusia lenticularis.

6w. (For stratigraphic position and association, see p. 140.) Middle Cambrian: Limestone at Seal Point Cove, near Long Point, Trinity Bay, Newfoundland (C. D. Walcott, S. W. Loper, and J. P. Howley, 1899).

Acrotreta sagittalis.

6y. (For stratigraphic position and association, see p. 140.) Upper Cambrian: Sandstone on north side of Random Island, between Birch and Sandy points, Smith Sound, Trinity Bay, Newfoundland (C. D. Walcott and S. W. Loper, 1899).

**Lingulella randomensis*.

7. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Shaly beds about 1,000 feet (305 m.) above the quartzitic beds, Silver Canyon, White Mountain Range, Inyo County, Cal. (C. D. Walcott, 1894).

Kutorgina perugata.

Yorkia wanneri?

7d. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales in second cliff, 0.125 mile (0.2 km.) west of Peak post office, 3 miles (4.8 km.) south of Clinton, Briceville quadrangle (U. S. G. S.), Anderson County, Tenn.

Obolus lamborni.

Lingulella ino.

7i. (For stratigraphic position and association, see p. 139.) Middle Cambrian: Limestone just west of the summit, on the road east of Schellbourne, Schell Creek Range, White Pine County, Nev. (J. E. Spurr, 1899).

Obolus rotundatus.

Lingulella manticula.

| *Lingulella punctata*.

| *Acrotreta idahoensis alta*.

7j. Middle Cambrian: Limestones at the north end of the Quinn Canyon Range, 1 mile (1.6 km.) northwest of the Italian Ranch foothills, Nye County, Nev. (J. E. Spurr, 1899).

Micromitra 2 sp. undt.

Obolus rotundatus.

Lingulella manticula.

°*Lingulella similis*.

| **Acrotreta cf. idahoensis*.

| °*Acrotreta primæva*?

| °*Acrotreta pyxidicula*.

Fossils marked ° may not all be from the same bed or even from the same approximate stratigraphic horizon.

- 7k** (see 31 and 333b). (For stratigraphic position and association, see p. 158.) Middle Cambrian: Shales in the dumps of the Half-moon and Chisholm mines, southwest slope of Ely Mountains, 3 miles (4.8 km.) northwest of Pioche, Lincoln County, Nev. (J. E. Spurr, 1899).
Obolus (*Westonia*) *ella*.
- 7n.** Upper? Cambrian: Limestone at Hornet Spring in the Spring Mountain Range, on the road from Indian Spring to Pahrump Valley, Lincoln County, Nev. (J. E. Spurr, 1899).
 **Obolus* sp. undt. b.
- 7r** (see 7s and 7v). Middle Cambrian: Calcareous shales 4 miles (6.4 km.) south-southeast of Emigrant Peak, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (H. W. Turner, 1899).
Obolus mcconnelli decipiens.
 **Acrothele turneri*.
- 7s** (see 7r and 7v). Upper Cambrian: Shales of the Emigrant formation [Turner, 1902, p. 265], 4 miles (6.4 km.) south-southeast of Emigrant Peak, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (H. W. Turner, 1899).
Obolus mcconnelli pelias.
- 7v** (see 7r and 7s). Upper Cambrian: Shales of the Emigrant formation [Turner, 1902, p. 265], 4.25 miles (6.8 km.) south-southeast of Emigrant Peak, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (H. W. Turner, 1899).
 **Obolus mcconnelli decipiens*.
Acrotreta argenta.
- 7w.** (For stratigraphic position and association, see p. 156.) Middle Cambrian: Limestone in Rock Canyon in the Wasatch Mountains, east of Provo, Utah County, Utah (G. H. Girty, 1900).
 **Nisusia* (*Jamesella*) *utahensis*.
Dorypyge?
- 7x** (=7y; 50 feet below 8a). Upper Cambrian: Limestone of the Emigrant formation [Turner, 1902, p. 265], about 2.5 miles (4 km.) southeast of Emigrant Pass, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (F. B. Weeks, 1900).
Obolus mcconnelli decipiens.
 **Obolus* (*Fordinia*) *bellulus*.
Lingulella desiderata.

Lingulella desiderata.
Lingulella (*Lingulepis*) *acuminata*.
 | *Acrotreta argenta*.
 | *Menocephalus*.
- 7z.** Upper Cambrian: Limestone of the Emigrant formation [Turner, 1902, p. 265], about 3 miles (4.8 km.) southeast of Emigrant Pass, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (F. B. Weeks, 1900).
Obolus (*Fordinia*) *bellulus*.
Lingulella desiderata.
Lingulella (*Lingulepis*) *acuminata*.
- 8a** (50 feet above 7x). Upper Cambrian: Shaly limestones of the Emigrant formation [Turner, 1902, p. 265], 2 miles (3.2 km.) southeast of Emigrant Pass, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (F. B. Weeks, 1900).
Obolella?
- 8b.** Lower Cambrian: Limestone in Tollgate Canyon, about 15 miles (24.1 km.) east of White Pine, White Mountain Range, Inyo County, Cal. (C. D. Walcott, 1894).
Kutorgina sp.
Obolella vermilionensis.
 **Wimanela inyoensis*.
- 8b'.** Upper Cambrian: Shales of the Emigrant formation [Turner, 1902, p. 265], in a ravine on the east side of the road about 1 mile (1.6 km.) southwest of Emigrant Pass, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (F. B. Weeks, 1900).
 **Acrotreta argenta*.
- 8d** (see 372). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales at Upper Leitches Creek, eastern Cape Breton, Nova Scotia (S. W. Loper, 1900).
Lingulella concinna.

- 8e. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone in Patterson Canyon, west side of the Schell Creek Range, White Pine County, Nev. (F. B. Weeks, 1900).
Lingulella manticula.
- 8f. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone at summit of canyon 10 miles (16.1 km.) south of Egan Canyon, east side of Egan Range, White Pine County, Nev. (F. B. Weeks, 1900).
Obolus discoideus. | Lingulella punctata.
Lingulella manticula. | Eoorthis?.
- 8g (=3s and 3t, which see). (For stratigraphic position and association, see p. 156.) (F. B. Weeks, 1900.)
Obolus mcconnelli pelias.
Acrothele subsidua.
- 8i. (For stratigraphic position and association, see p. 156.) Middle Cambrian: Shales believed to be referable to the lower portion of the Marjum limestone [Walcott, 1908f, p. 180], found about 0.5 mile (0.8 km.) east of Antelope Springs, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (F. B. Weeks, 1900).
Micromitra sculptilis.
Obolus mcconnelli pelias.
Kutorgina sp.
- 8j. Middle Cambrian: About 575 feet (175.3 m.) above the unconformable base of the Cambrian, in a shale which corresponds in position to shale No. 4 of the Dearborn River section [see Walcott, 1908f, p. 202], on the ridge between Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. G. S.), Powell County, Mont. (C. D. Walcott, 1905).
Micromitra (Paterina) superba. | Ptychoparia sp.
Obolus mcconnelli pelias. | Zacanthoides sp.
Bathyriscus productus? (Hall and Whitfield).
- 8k. (For stratigraphic position and association, see p. 156.) Middle Cambrian: Shales 0.5 mile (0.8 km.) northwest of Tyler Springs, east slope of House Range, east of Antelope Springs [Walcott, 1908f, Pl. XIII], Millard County, Utah (F. B. Weeks, 1900).
Obolus mcconnelli pelias.
- 8m. (For stratigraphic position and association, see p. 139.) Middle Cambrian: Limestone near the south end of the high ridge 4 miles (6.4 km.) northeast of Osceola, White Pine County, Nev. (F. B. Weeks, 1900).
Obolus mcconnelli.
Obolus mcconnelli decipiens.
- 8n. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone about 500 feet (152 m.) up in the Cambrian limestones east of Swallow ranch, west side of the Snake Range, 20 miles (32.2 km.) south of Osceola, White Pine County, Nev. (F. B. Weeks, 1900).
Lingulella desiderata.
- 8o. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone on the slope of the ridge where the range swings around to the northwest, 2 miles (3.2 km.) north of Aurum, Schell Creek Range, White Pine County, Nev. (F. B. Weeks, 1900).
* Micromitra sculptilis endlichi. | Lingulella punctata.
Micromitra sp. | Acrotreta microscopica.
Obolus rotundatus. | Eoorthis sp.
- 8p. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone halfway up the canyon east of McGill's ranch, on the west side of the Schell Creek Range, 14 miles (22.5 km.) northeast of Ely, White Pine County, Nev. (F. B. Weeks, 1900).
Obolus rotundatus?.
- 8q. Lower Cambrian: Shales near the contact between the Cambrian and the Triassic, 2 miles (3.2 km.) northwest of York, York County, Pa. (A. Wanner, 1900).
Obolus sp.
Olenellus thompsoni rudis Walcott.
- 8r. Upper Cambrian: Shales of the Emigrant formation [Turner, 1902, p. 265], about 8 miles (12.8 km.) southeast of Emigrant Peak, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (H. W. Turner).
Obolus mcconnelli decipiens.
- 8v. (For stratigraphic position and association, see p. 146.) Lower Cambrian: Shales in upper portion of *Holmia kjerulfi* zone, Ringsaker, near Lake Mjøsen, Province of Hedemarken, Norway (Schmalensee, 1900).
Obolus mobergi.
* Acrothele bellapunctata.

8w (see 310 I, 320f, and 321y). (For stratigraphic position and association, see p. 145.) Middle Cambrian: Limestones of *Paradoxides forchhammeri* zone, at Andrarum, 20 miles (32 km.) northwest of Simrishamn, Province of Christianstad, Sweden (Schmalensee, 1900).

| Lingulella sp. | Elyx laticeps Angelin. |
| Acrothele coriacea. | Solenopleura holometopa Angelin. |

8x. (For stratigraphic position and association, see p. 144.) Passage beds between the Upper Cambrian and the Ordovician: *Ceratopyge* limestone at the cement works at Slemmestad, in Røken, about 3 miles (4.8 km.) southwest of Christiania, Norway (Schmalensee, 1900).

| | |
|-----------------------------|---------------------------------|
| Obolus (Bröggeria) salteri. | Acrotreta socialis. |
| Lingulella lepis. | Eoorthis daunus. |
| Lingulella sp. | Eoorthis wimani. |
| Acrothele coriacea. | Ceratopyge forficula Sars. |
| *Acrotreta seebachi. | Triarthrus angelini Linnarsson. |

8y. (For stratigraphic position and association, see p. 146.) Lower Cambrian: With *Torellella laevigata* in the "Sparagmite" sandstone, at Skårösen, northwest Dalarna, Province of Kopparberg, Sweden (Schmalensee, 1900).

Lingulella nathorsti.
Torellella laevigata Linnarsson.

8z. (For stratigraphic position and association, see p. 146.) Middle Cambrian: Limestones of *Paradoxides olandicus* zone, Borgholm, Oeland Island, Sweden (Schmalensee, 1900).

| | |
|------------------------------------|---------------------------------------|
| Acrothele (Redlichella) granulata. | Liostracus aculeatus Angelin. |
| Acrotreta socialis. | Ellipsocephalus polytomus Linnarsson. |
| Acrotreta sp. | |

9 (same horizon as 9a). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone on southeastern slope of ridge 1 mile (1.6 km.) north of the northwest corner of Harlan Knob, about 4 miles (6.4 km.) northeast of Rogersville [see Keith, 1905, areal geology sheet], Hawkins County, Tenn. (C. D. Walcott, 1891).

Lingulella desiderata.

9a (same horizon as 9). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone on the south shore of Holston River, at Melinda Ferry, 5 miles (8 km.) southwest of Rogersville [see Keith, 1896a, areal geology sheet], Hawkins County, Tenn. (C. D. Walcott, 1891).

Lingulella desiderata.
Lingulella similis.

9d. (For stratigraphic position and association, see p. 143.) Upper Cambrian: *Obolus* sandstone at Jaggowal, about 20 miles (32.2 km.) east-southeast of Reval, Government of Esthonia, Russia (Schmalensee, 1900).

Obolus apollinis.
Obolus triangularis.
Keyserlingia buchi.

9e. (For stratigraphic position and association, see p. 145.) Upper Cambrian: Sandstone in the *Obolus* conglomerate at Boda, north of Rattvik, Dalarna, Sweden (Schmalensee, 1900).

Obolus apollinis.

9f. (For stratigraphic position and association, see p. 145.) Upper Cambrian: Limestones of the *Olenus* zone at Nørnsnæs, west of Christiania, Norway (Schmalensee, 1900).

Lingulella lepis.
Orusia lenticularis.
Peltura scarabæoides Wahlenberg.

9h (limestone above the Wolsey shale). Middle Cambrian: Limestone on Beaver Creek, 5 miles (8 km.) north of York, about 8 miles (12.8 km.) north of Canon Ferry, Big Belt Mountains, Fort Logan quadrangle (U. S. G. S.), Meagher County, Mont. (C. D. Walcott, 1900).

| | |
|--------------------|--------------------------|
| Micromitra pealei. | Acrotreta attenuata. |
| Obolella?. | Billingsella plicatella. |

9k. Middle Cambrian: Limestone forming 1c of the Dearborn River section [Walcott, 1908f, p. 201], on North Fork of Dearborn River, in the eastern part of the Lewis and Clark National Forest, Lewis and Clark County, Mont. (C. D. Walcott, 1900).

*Dearbornia clarki.

- 9m. Middle Cambrian: Shale 4 miles (6.4 km.) above Walker's ranch, on North Fork of Dearborn River, in the eastern part of the Lewis and Clark National Forest, Lewis and Clark County Mont. (C. D. Walcott, 1900).
Obolus (*Westonia*) *ella*.
- 9n (=326e). Lower Cambrian: Dark purplish siliceous shales on Pearl Street, North Weymouth, Norfolk County, Mass. (H. T. Burr, 1900).
Obolella atlantica.
Callavia hurri Walcott.
Callavia crosbyi Walcott.
- 9o. Middle Cambrian: Siliceous limestone about 15 feet (4.6 m.) above the Coronado quartzite [Lindgren, 1905, p. 3], 0.5 mile (0.8 km.) southwest of Milk ranch, on the first spur north of the one which the main road follows, Clifton quadrangle (U. S. G. S.), Graham County, Ariz. (J. M. Boutwell, 1901).
Lingulella lineolata.
Lingulella perattenuata.
- 9p (about 115 feet above 9r; 55 feet above 12s; almost same horizon as 9x; 10 feet below 9t). (For stratigraphic position and association, see p. 142.) Upper Cambrian: About 160 feet (48.8 m.) above the porphyry contact in the limestone of the Reagan sandstone, in SE. $\frac{1}{4}$ NE. $\frac{1}{4}$ sec. 2, T. 4 N., R. 13 W., about 15 miles (24.2 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).
Obolus tetonensis ninus. | *Ptychoparia* sp.
 **Lingulella ora*. | *Chariocephalus* sp.
Linnarssonella girtyi. | *Illænurus* sp.
- 9q (50 feet below 12d). (For stratigraphic position and association, see p. 142.) Upper Cambrian: About 10 feet (3 m.) above the porphyry contact and 90 feet (27.4 m.) below the Arbuckle limestone, in limestone of the Reagan sandstone, in middle of west half of sec. 2, T. 4 N., R. 13 W., about 15 miles (24.2 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).
Obolus tetonensis ninus. | *Eoorthis wichitaensis*.
Lingulella ora. | *Agnostus* sp.
Lingulella (*Lingulepis*) *acuminata*. | *Agraulos* sp.
Linnarssonella girtyi. | *Ptychoparia* sp.
Linnarssonella girtyi?. | *Pterocephalus* sp.
- 9r (about 125 feet below 9t; about 115 feet below 9p; see 9v). (For stratigraphic position and association, see p. 142.) Upper Cambrian: About 45 feet (14 m.) above the porphyry contact in the limestone of the Reagan sandstone, in SE. $\frac{1}{4}$ NE. $\frac{1}{4}$ sec. 2, T. 4 N., R. 13 W., 15 miles (24.2 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).
 **Obolus tetonensis ninus*. | *Acrotreta microscopica*.
Lingulella similis. | *Agnostus* sp.
Linnarssonella girtyi. | *Ptychoparia* sp.
- 9s (believed to just overlie 9u). (For stratigraphic position and association, see p. 142.) Upper Cambrian: About 85 feet (26 m.) below the Arbuckle limestone, in the limestone of the Reagan sandstone, near middle of west half of sec. 13, T. 4 N., R. 13 W., 13 miles (20.8 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).
Obolus tetonensis ninus. | *Lingulella* (*Lingulepis*) *acuminata*.
Lingulella similis. | *Eoorthis wichitaensis*.
- 9t (125 feet above 9r; 10 feet above 9p; 25 feet below 9u; see 9v). (For stratigraphic position and association, see p. 142.) Upper Cambrian: About 170 feet (52 m.) above the porphyry contact in the limestone of the Reagan sandstone, SE. $\frac{1}{4}$ NE. $\frac{1}{4}$ sec. 2, T. 4 N., R. 13 W., 15 miles (24.2 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).
Obolus matinalis. | *Acrotreta microscopica*.
Obolus tetonensis ninus. | *Eoorthis indianola*.
Lingulella similis. | *Ptychoparia* sp.
- 9u (believed to just underlie 9s; 25 feet above 9t). (For stratigraphic position and association, see p. 142.) Upper Cambrian: About 195 feet (59.4 m.) above the porphyry contact in the limestone of the Reagan sandstone, in SE. $\frac{1}{4}$ NE. $\frac{1}{4}$ sec. 2, T. 4 N., R. 13 W., 15 miles (24.2 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).
Obolus tetonensis ninus. | *Syntrophia primordialis*.
Lingulella similis. | *Agnostus* sp.
Eoorthis indianola. | *Ptychoparia* sp.
Eoorthis wichitaensis.

9v (150 feet below 9w; between 9r and 9t). (For stratigraphic position and association, see p. 142.) Upper Cambrian: Limestone of the Reagan sandstone about 250 feet (76 m.) below the Arbuckle limestone, SW. $\frac{1}{4}$ sec. 17, T. 4 N., R. 12 W., about 11 miles (17.7 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).

Lingulella (*Lingulepis*) *acuminata*.
Linnarssonella *girtyi*.
Agnostus sp.

Agraulos sp.
Chariocephalus? sp.
Illænurus? sp.

9w (150 feet above 9v). (For stratigraphic position and association, see p. 142.) Upper Cambrian: Limestone of the Reagan sandstone about 100 feet (30.5 m.) below the Arbuckle limestone, SW. $\frac{1}{4}$ sec. 17, T. 4 N., R. 12 W., 11 miles (17.7 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).

Eoorthis *indianola*.
Agnostus.

9x (almost same horizon as 9p). (For stratigraphic position and association, see p. 142.) Upper Cambrian: Sandstones lying between beds of quartzite underlying the 300 feet of limestone at the top of the Reagan sandstone, SW. $\frac{1}{4}$ sec. 17, T. 4 N., R. 12 W., about 11 miles (17.7 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).

Dicellomus *politus*.

9z. (For stratigraphic position and association, see p. 142.) Upper Cambrian: Basal beds of the Arbuckle limestone, about 25 feet above the heavy bedded limestone, near the middle of the west half of sec. 13, T. 4 N., R. 13 W., about 13 miles (20.8 km.) northwest of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).

Eoorthis *wichitaensis*.
Dikellocephalus.

10a (see 106). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandy layers of the Rome formation in western railroad cut through Shooks Gap, in Bays Mountains, 10 miles (16.1 km.) southeast of Knoxville [see Keith, 1895, areal geology sheet], Knox County, Tenn. (C. D. Walcott, 1891).

**Obolus* *pandemia*.
**Lingulella* *auga*.
Lingulella *similis*.

10b. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandy layers of the Rome formation at the western end of the central railroad cut through Shooks Gap, in Bays Mountains, 10 miles (16.1 km.) southeast of Knoxville [see Keith, 1895, areal geology sheet], Knox County, Tenn. (C. D. Walcott, 1891).

Lingulella *auga*.

10c (50 feet below 10k). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales on west side of Barachois River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).

Obolus (*Bröggeria*) *salteri*.
Lingulella *concinna*.

Schizambon *priscus*?
Acrotreta *bisecta*.

10d. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales on west side of Barachois River, 0.125 mile (0.2 km.) north of Boisdale road, opposite McMullin's place, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).

Obolus (*Bröggeria*) *salteri*.
Lingulella *concinna*.

Schizambon *priscus*.
Acrotreta *bisecta*.

10e (50 feet above 10f). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales on the east branch of Barachois River, 0.5 mile (0.8 km.) north of the crossroad from Boisdale to Upper Leitches Creek, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).

Obolus (*Bröggeria*) *salteri*.
Lingulella *concinna*.
Schizambon *priscus*.

Acrotreta *bisecta*.
Acrotreta *convexa*.

10f (=10g; 50 feet below 10e). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales on the east branch of Barachois River, 0.75 mile (1.2 km.) north of the crossroad from Boisdale to Upper Leitches Creek, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).

Obolus (*Bröggeria*) *salteri*.
Lingulella *concinna*.
Schizambon *priscus*.

Acrothele sp.
Acrotreta *bisecta*.

10g (=10f). (For stratigraphic position and association, see p. 131.) (S. W. Loper, 1901.)

Obolus (*Bröggeria*) *salteri*.
Lingulella *concinna*.
Schizambon *priscus*.

Acrotreta *bisecta*.
Acrothyra *proavia*.

- 10h.** (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale on small east branch of Barachois River, 0.75 mile (1.2 km.) north of the crossroad from Boisdale to Upper Leitches Creek, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- | | |
|----------------------|----------------------|
| Lingulella concinna. | Acrotreta bisecta. |
| Schizambon priscus. | Orusia lenticularis. |
- 10i.** (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale in high bank on west side of Barachois River, just north of the Boisdale road, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- | | |
|-----------------------------|---------------------|
| Obolus (Bröggeria) salteri. | Schizambon priscus. |
| Lingulella concinna. | Acrotreta convexa. |
- 10k** (50 feet above 10c). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale on west bank of Barachois River, about 0.25 mile (0.4 km.) north of the Boisdale road, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- Schizambon priscus.
- 10l.** (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale on east bank of Barachois River, 6 miles (9.6 km.) from Little Bras d'Or Lake, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- | | |
|-----------------------------|--------------------|
| Obolus (Bröggeria) salteri. | Acrotreta bisecta. |
| Lingulella concinna. | Acrotreta convexa. |
| Schizambon priscus. | |
- 10m** (see 372a). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales 2 miles (3.2 km.) south of the Boisdale road from Upper Leitches Creek, toward the head of Barachois River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- Obolus (Bröggeria) salteri.
Lingulella concinna.
- 10n.** (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale in ravine on east side of Barachois Glen, 3 miles (4.8 km.) from Barachois, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- Obolus (Bröggeria) salteri.
Lingulella concinna.
Acrotreta bisecta.
- 10o.** (For stratigraphic position and association, see p. 132.) Middle? Cambrian: Arenaceous shales in the railroad cut on the shore of Bras d'Or Lake, at Barachois, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- Obolus (Westonia) escasoni?.
- 10p** (a little below 10q; see 344o). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstone just below the waterfall in Division E2b of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- | | |
|-----------------------------------------|------------------------------------|
| Obolus (Palæobolus) bretonensis. | Acrothele avia. |
| Lingulella atava. | Acrotreta gemmula. |
| Lingulella collicia. | Acrothyra proavia. |
| Lingulella triparilis. | Acrothyra sera. |
| Lingulella sp. | Acrothyra signata. |
| Lingulella (Lingulepis) gregwa. | Acrothyra signata orta. |
| Lingulella (Lingulepis) gregwa robusta. | *Protorthis (Loperia) dugaldensis. |
| Lingulella (Lingulepis) longinervis. | |
- Matthew [1903, p. 25] gives the following as occurring in Division 2b:
- | | |
|-----------------------------------------|--------------------------------------|
| Acrothyra signata tarda=Acrothyra sera. | Orthotheca. |
| Lingulepis longinervis. | Bradorona perspicator magna Matthew. |
- Bassler cites the following from this locality:
- | | |
|--------------------------------|------------------------------------|
| Bradoria acuta (Matthew). | Bradoria perspicator (Matthew) ss. |
| Bradoria benepuncta (Matthew). | Bradoria robusta (Matthew). |
| Bradoria ovalis (Matthew). | Bradoria spectator (Matthew). |
- 10p'.** (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstone 0.25 mile (0.4 km.) from lower bridge, on Gregwa Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- | | |
|-----------------------------------------|--------------------------------------|
| Lingulella (Lingulepis) gregwa. | Lingulella (Lingulepis) longinervis. |
| Lingulella (Lingulepis) gregwa robusta. | Acrothyra sera. |

- 10p''.** (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstone on the small brook on the hill between the bridge over Indian River and McPhees Brook, Cape Breton, Nova Scotia (S. W. Loper, 1901).
- | | |
|-----------------------------------------------------------------|------------------------------------|
| Obolus (<i>Palæobolus</i>) <i>bretonensis</i> . | <i>Acrotreta gemmula</i> . |
| <i>Lingulella</i> (<i>Lingulepis</i>) <i>gregwa</i> . | <i>Acrothyra sera</i> . |
| <i>Lingulella</i> (<i>Lingulepis</i>) <i>gregwa robusta</i> . | <i>Bradoria robusta</i> (Matthew). |
| <i>Lingulella</i> (<i>Lingulepis</i>) <i>longinervis</i> . | <i>Bradoria obesa</i> (Matthew). |
| <i>Acrothele avia</i> . | |
- 10q** (a little above 10p; see 344). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstone below the waterfall in Division E2b of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- Acrothyra proavia*.
- Matthew [1903, p. 25] cites the following species from Division 2b:
- | | |
|----------------------------------------------------------|---------------------------------------------|
| <i>Acrothyra signata tarda</i> = <i>Acrothyra sera</i> . | <i>Orthotheca</i> . |
| <i>Lingulepis longinervis</i> . | <i>Bradorona perspicator magna</i> Matthew. |
- Bassler cites the following from this locality:
- Bradoria elongata* n. sp.
- 10r.** (For stratigraphic position and association, see p. 131.) Upper Cambrian: Arenaceous shales of Division C3a? of Matthew at McAdam shore, East Bay, east of Bras d'Or Lake, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- | | |
|---------------------------------------------------|----------------------------------------------|
| Obolus (<i>Bröggeria</i>) <i>salteri</i> . | Obolus (<i>Westonia</i>) <i>escasoni</i> ? |
| Obolus (<i>Palæobolus</i>) <i>bretonensis</i> . | * <i>Lingulella lens</i> . |
- 10s.** (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstone on McLean Brook, near Marion Bridge, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- Lingulella cania*.
- Lingulella* (*Lingulepis*) *exigua*.
- Beyrichona triceps* Matthew.
- 10t.** (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstone on McLean Brook, near Marion Bridge, eastern Cape Breton, Nova Scotia (S. W. Loper, 1901).
- Lingulella* (*Lingulepis*) *exigua*.
- 10v.** Upper Cambrian: Shales in the "St. Croix sandstone" at Fox Glen, about 8 miles (12.8 km.) east of Baraboo, Baraboo quadrangle (U. S. G. S.), Sauk County, Wis.
- *Obolus *pheres*.
- Lingulella winona*.
- **Acrotreta nox*.
- 10w.** (For stratigraphic position and association, see p. 139.) Middle Cambrian: Shaly limestones about 5 miles (8 km.) northeast of Osceola, on the east side of the Snake Range, White Pine County, Nev. (C. D. Walcott, 1903).
- Micromitra sculptilis*.
- Obolus *mcconnelli*.
- 10y** (same horizon as 10z). (For stratigraphic position and association, see p. 155.) Middle Cambrian: About 2,900 feet (884 m.) above the Lower Cambrian and 1,500 feet (457.2 m.) below the Upper Cambrian, in the central part of the limestone forming 1a of the Marjum limestone [Walcott, 1908f, p. 179], about 1 mile (1.6 km.) south-southwest of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (C. D. Walcott and F. B. Weeks, 1903).
- | | |
|--------------------------------|------------------------------|
| <i>Micromitra sculptilis</i> . | <i>Acrotreta attenuata</i> . |
| Obolus <i>mcconnelli</i> . | <i>Aagnostus</i> . |
| <i>Lingulella arguta</i> . | <i>Ptychoparia</i> . |
| <i>Acrothele subsidua</i> . | <i>Anomocare</i> . |
- 10z** (same horizon as 10y). (For stratigraphic position and association, see p. 155.) Middle Cambrian: About 2,900 feet (884 m.) above the Lower Cambrian and 1,500 feet (457.2 m.) below the Upper Cambrian, in the central part of the limestone forming 1a of the Marjum limestone [Walcott, 1908f, p. 179], in the long cliff about 2 miles (3.2 km.) southeast of Marjum Pass [see Walcott, 1908f, Pls. XIII and XV], House Range, Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1903 and 1905).
- | | |
|----------------------------------|--------------------------|
| * <i>Dicellomus prolificus</i> . | <i>Ptychoparia</i> 2 sp. |
| * <i>Acrotreta bellatula</i> . | <i>Agraulos</i> . |
| <i>Aagnostus</i> 2 sp. | <i>Anomocare</i> . |

11. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandstones and shales of the Rome formation, about 1 mile (1.6 km.) east of Post Oak Springs [see Hayes, 1894, areal geology sheet], Roane County, Tenn. (C. D. Walcott, 1891).

Lingulella ino.

*Lingulella tarpa.

- 11a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandstone between First and Armstrong creeks, in the southeast corner of the Maynardville quadrangle (U. S. G. S.), Union County, Tenn. (C. D. Walcott, 1891).

Obolus sinoe.

Lingulella tarpa.

Dicellomus appalachia.

- 11c. Upper Cambrian: Hardyston quartzite [Weller, 1900, pp. 110 and 112], O'Donnell and McManniman's quarry, Newton, Sussex County, N. J. (H. E. Diekhaut, 1901).

*Lingulella welleri.

Weller [1900, p. 12] cites the following from this locality:

Foraminifera?.

Lingulella stoneana=Obolus (Westonia) stoneanus.

*Orthis newtonensis=Eoorthis newtoneusis.

Microdiscus? sp.

Olenellus? sp.

Ptychoparia newtonensis Weller.

Ptychoparia 2 sp. undt.

Anomocare parvula Weller.

Dikellocephalus newtonensis Weller.

- 11d. (For stratigraphic position and association, see p. 137.) Upper Cambrian: Arenaceous limestone about 2 miles (3.2 km.) north of Montana, in sec. 22, T. 35 N., R. 1 E., Iron County, Mo. (D. K. Greger).

Obolus matinalis?.

Billingsella coloradoensis.

Eoorthis remnicha texana?.

- 11e. (For stratigraphic position and association, see p. 137.) Middle Cambrian: In thin-bedded limestones south-southwest of Potosi, Washington County, Mo. (D. K. Greger).

Obolus matinalis?.

Lingulella similis.

Lingulella sp.

Linnarssonella girtyi.

Acrotreta microscopica missouriensis.

Billingsella coloradoensis.

- 11j. (For stratigraphic position and association, see p. 137.) Middle Cambrian: Basal part of Bonnetterre limestone, Mine Lamotte, Madison County, Mo. (E. O. Ulrich, 1904).

*Obolus lamborni.

Obolus sinoe.

Lingulella acutangula.

Dicellomus nanus.

- 11k. (For stratigraphic position and association, see p. 137.) Middle Cambrian: In sandstones and limestones of the "Edgewise beds," St. Francois County, Mo. (F. Nason, 1901).

Lingulella acutangula.

Linnarssonella girtyi.

*Acrotreta microscopica missouriensis.

- 11l. (For stratigraphic position and association, see p. 137.) Upper Cambrian: Arenaceous limestone of the Elvins formation, 50 feet (15.2 m.) above the "Edgewise beds," St. Francois County, Mo. (F. Nason, 1901).

Lingulella acutangula?.

Billingsella coloradoensis.

Eoorthis remnicha texana?.

- 11m. (For stratigraphic position and association, see p. 137.) Middle Cambrian: Drill cores of limestone in the Bonnetterre limestone, at horizons 10 and 20 feet (3 and 6 m.) above the Lamotte sandstone, at Flat River, St. Francois County, Mo. (F. Nason, 1901).

Micromitra sp.

Micromitra (Paterina) cf. stissingensis.

Obolus lamborni.

Lingulella cf. ora.

Dicellomus nanus.

Dicellomus politus.

- 11n. (For stratigraphic position and association, see p. 155.) Middle Cambrian: About 3,000 feet (914.4 m.) above the Lower Cambrian and 1,400 feet (426.7 m.) below the Upper Cambrian, in the upper part of the limestone forming Ia of the Marjum limestone [Walcott, 1908f, p. 179], in the long cliff 2 miles (3.2 km.) south-east of Marjum Pass [see Walcott, 1908f, Pls. XIII and XV], House Range, Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1903 and 1905).

Obolus mcconnelli pelias.

*Obolus (Fordinia) gilberti.

Acrotreta bellatula.

*Acrotreta marjumensis.

*Acrotreta cf. sagittalis.

Agnostus 4 sp.

- 11o.** (For stratigraphic position and association, see p. 155.) Middle Cambrian: About 2,750 feet (838.2 m.) above the Lower Cambrian and 1,650 feet (502.9 m.) below the Upper Cambrian, in limestone at the base, 1a, of the Marjum limestone [Walcott, 1908f, p. 179], about 4 miles (6.4 km.) southeast of Antelope Springs, in the spur at the junction of the Deseret and Swasey Spring roads [Walcott, 1908f, Pl. XIII], House Range, Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1903 and 1905).

Micromitra (*Iphidella*) *pannula ophirensis*.
Obolus mcconnelli pelias.
Obolus rotundatus.
Acrotreta idahoensis.
 Annelid trails.

Stenothecca sp.
Hyalolithes.
Bathyriscens?.
Ptychoparia 2 sp.
Anomocare.

- 11p.** (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 2,000 feet (609.6 m.) above the Lower Cambrian and 2,400 feet (731.5 m.) below the Upper Cambrian, in the limestones forming 1e of the Marjum limestone [Walcott, 1908f, p. 181], in the long cliff about 2.5 miles (4 km.) southeast of Marjum Pass [Walcott, 1908f, Pls. XIII and XV], House Range, Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).

Linnarssonella sp.
Sponge spiculæ.
Agnostus, several sp.

Ogygopsis?.
Ptychoparia 2 sp.

- 11q** (=11y and 30g; same horizon as 3w). (For stratigraphic position and association, see p. 156.) (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1903 and 1905.)

**Obolus mcconnelli pelias*.
Lingulella arguta.
Acrothele subsidua.
Nisusia (Jamesella) nautes?.
Nisusia (Jamesella) spencei.
Eoorthis thyone.

Neolenus inflatus Walcott.
Neolenus intermedius Walcott.
Neolenus intermedius pugio Walcott.
Neolenus superbus Walcott.
Ogygopsis?

- 11s.** (For stratigraphic position and association, see p. 157.) Middle Cambrian: Shales just above Simpson Spring, about 20 miles (32.2 km.) west-southwest of Vernon, on the stage road from Vernon to Fish Spring, Tooele County, Utah (C. D. Walcott, 1903).

Obolus (Westonia) ella?.
Micromitra sculptilis.

- 11u.** (For stratigraphic position and association, see p. 156.) Middle Cambrian: Lower portion of the shales forming the Wheeler formation, in Rainbow Valley, House Range [see Walcott, 1908f, Pl. XIII], Millard County, Utah (C. D. Walcott, 1903).

Acrothele subsidua.

- 11w** (=30c). (For stratigraphic position and association, see p. 157.) Middle Cambrian: About 1,050 feet (320 m.) above the Lower Cambrian and 3,350 feet (1,021.1 m.) below the Upper Cambrian, in the shales forming 1d of the Swasey formation [Walcott, 1908f, p. 182], at the head of Dome Canyon, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (C. D. Walcott and F. B. Weeks, 1903).

Lingulella arguta.
Ptychoparia.

- 11x** (=3x). (For stratigraphic position and association, see p. 156.) (C. D. Walcott, 1903.)

Obolus rotundatus.
Lingulella arguta.

- 11y** (=11q and 30g). (For stratigraphic position and association, see p. 156.) (C. D. Walcott, 1903.)

Lingulella arguta.
Acrothele subsidua.
Acrotreta cf. ophirensis.

- 11z.** (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstone on Big Ridge 2 miles (3.2 km.) south of Marion Bridge, on the canal of John McDougald, eastern Cape Breton, Nova Scotia (S. W. Loper).

Obolus (Westonia) escasoni.
Lingulella (Lingulepis) exigua.

- 12.** (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandy shale on Webbs Ridge, in gap west of Simpson's farm, 6 miles (9.6 km.) northeast of Knoxville, Knox County, Tenn. (C. D. Walcott, 1891).

Linnarssonella tennesseensis.

12j (50 feet below 12g; 40 feet above 12i). (For stratigraphic position and association, see p. 142.) Upper Cambrian: Lower part of Arbuckle limestone, second fossiliferous horizon in the section at Small Hill, 2 miles (3.2 km.) southwest of Signal Mountain, about 8 miles (12.8 km.) west of Fort Sill, Comanche County, Okla. (E. O. Ulrich, 1901).

Eoorthis wichitaensis.
Agraalos sp.
Dikellocephalus sp.

Ptychaspis sp.
Illænurus sp.

12k (15 feet below 12n in Springer section). (For stratigraphic position and association, see p. 142.) Upper Cambrian: Limestone of the Reagan sandstone, about 225 feet (69 m.) above the porphyry contact and 55 feet (17 m.) below the Arbuckle limestone, on the west side of Honey Creek, near southeast corner sec. 35, T. 1 S., R. 1 E., 7 miles (11.2 km.) north of Springer, Ardmore quadrangle (U. S. G. S.), Carter County, Okla. (E. O. Ulrich, 1901).

Obolus tetonensis ninus.
Lingulella similis.
Acrotreta microscopica.
*Eoorthis indianola.

Eoorthis remnicha.
Eoorthis wichitaensis.
Eoorthis wichitaensis læviusculus.
Chariocephalus sp.

12m. (For stratigraphic position and association, see p. 142.) Upper Cambrian: Arbuckle limestone [in the section 7 miles (11.2 km.) north of Springer this horizon is about 30 feet (9.1 m.) above the Reagan sandstone], NE. $\frac{1}{4}$ sec. 2, T. 2 S., R. 1 E., Ardmore quadrangle (U. S. G. S.), Carter County, Okla. (E. O. Ulrich, 1901).

Obolus tetonensis ninus.
Lingulella similis.
Eoorthis remnicha texana.

Agraalos sp.
Ptychaspis sp.

12n (15 feet above 12k in Springer section). (For stratigraphic position and association, see p. 142.) Upper Cambrian: Limestone of the Reagan sandstone about 240 feet (73 m.) above the porphyry contact and 40 feet (12 m.) below the Arbuckle limestone, NW. $\frac{1}{4}$ sec. 1, T. 2 S., R. 1 E., 7 miles (11.2 km.) north of Springer, Ardmore quadrangle (U. S. G. S.), Carter County, Okla. (E. O. Ulrich, 1901).

Obolus tetonensis ninus.
Lingulella similis.
Lingulella (Lingulepis) acuminata.
Acrotreta microscopica.
Eoorthis indianola.
Eoorthis remnicha.

Eoorthis remnicha texana.
Eoorthis wichitaensis.
Eoorthis wichitaensis læviusculus.
Syntrophia primordialis.
Ptychoparia sp.
Chariocephalus sp.

12p. (For stratigraphic position and association, see p. 142.) Upper Cambrian: About 225 feet (69 m.) above the igneous rocks in the limestone of the Reagan sandstone, at the northwest extremity of the Arbuckle Mountains, about 4 miles (6.4 km.) east of Homer, Carter County, Okla.

Obolus tetonensis ninus.
Lingulella similis.
Lingulella (Lingulepis) acuminata.
Acrotreta curvata.
Acrotreta microscopica.
*Acrotreta ulrichi.
Linnarssonella girtyi.
Eoorthis indianola.

Eoorthis remnicha.
*Eoorthis wichitaensis.
*Eoorthis wichitaensis læviusculus.
Agraalos sp.
Ptychoparia sp.
Chariocephalus sp.
Illænurus sp.

12q. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Knox dolomite on Bunker Hill, 6 miles (9.6 km.) northeast of Rogersville [see Keith, 1905, areal geology sheet], Hawkins County, Tenn. (M. R. Campbell, 1892).

*Syntrophia campbelli.

12v. Lower Cambrian: Sandstone above the quartzite 1 mile (1.6 km.) west of Fruitville, on Little Conestoga Creek, Manheim Township, Lancaster County, Pa. (C. D. Walcott, 1909).

Obolella crassa?

13. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandstones of the Rome formation 1.5 miles (2.4 km.) east of Post Oak Springs [see Hayes, 1894, areal geology sheet], Roane County, Tenn. (C. D. Walcott, 1891).

Lingulella ino.
*Linnarssonella tennesseensis.

13b. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandstones of the Rome formation northeast of Rhea Springs [see Hayes, 1894, areal geology sheet], Roane County, Tenn. (C. D. Walcott, 1891).

Micromitra (Paterina) crenistria.
*Lingulella ino.

- 13c. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandstones of the Rome formation, west side of the sandstone ridge about 2.5 miles (4 km.) southwest of Rome [see Hayes, 1902, historical geology sheet], Floyd County, Ga. (C. D. Walcott, 1891).

Lingulella ino.

- 13d (=13d'). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones opposite the third waterfall in Dugald Brook, between Divisions E2a and E2b of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella (*Lingulepis*) *longinervis*.

Acrothele avia.

Bradoria robusta (Matthew).

- 13d' (=13d). (For stratigraphic position and association, see p. 134.) (S. W. Loper, 1903.)

Obolus (*Palæobolus*) *bretonensis*.

Acrothele avia.

Lingulella atava.

Acrothyra sera.

Lingulella collicia.

Acrothyra signata.

- 13d'' (see 13p, 13g, 13f, and 13p'). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones 10 feet (3 m.) below Division E2a of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella (*Lingulepis*) *longinervis*.

Acrothele prima.

Acrothele avia.

Acrothyra signata orta.

Bassler cites the following from this locality:

Bradoria benepuncta (Matthew).

Bradoria robusta (Matthew).

Bradoria perspicator (Matthew) (ss).

Bradoria rugulosa Matthew (emend.).

- 13e (see 344l). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones of Division E2c of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Obolus (*Palæobolus*) *bretonensis lens*.

Acrothyra proavia.

Acrothyra sera.

Matthew [1903, p. 25] gives the following fauna occurring in 2c:

Acrothyra signata orta.

Bradorona observator lævis Matthew.

- 13f (see 13p, 13g, 13d'', and 13p'). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones 20 feet (6 m.) above Division E2a of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella (*Lingulepis*) *longinervis*.

Acrothyra sera.

- 13g (see 13p, 13f, 13d'', and 13p'). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones 10 feet (3 m.) above Division E2a of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella (*Lingulepis*) *longinervis*.

Bassler cites the following species from this locality:

Hymenocaris? *matthewi* n. sp.

- 13h. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale on east bank of Barachois River, 1.5 miles (2.4 km.) north of Boisdale, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Obolus (*Bröggeria*) *salteri*.

Schizambon priscus.

Lingulella concinna.

Acrotreta bisecta.

- 13i (little different horizon than 13r). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstone of the "Johannian" Division of Matthew's section, on Gillis Brook, East Bay, east of Bras d'Or Lake, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella tumida.

- 13k (see 344f). (For stratigraphic position and association, see p. 135.) Middle Cambrian: Shales of Matthew's [1903, p. 15] Coldbrook, above the great falls in Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Micromitra (*Iphidella*) *pannula?*

Acrothyra sera.

**Obolus?* *torrentis*.

**Acrothyra signata prima*.

Lingulella (*Lingulepis?*) *pumila?*

- 131 (=131'). (For stratigraphic position and association, see p. 133.) (S. W. Loper, 1903.)

Obolus (*Palæobolus*) *bretonensis lens*.

Acrothele avia.

Lingulella (*Lingulepis*) *longinervis*.

Acrothyra proavia.

13l' (=13l; see 344i). (For stratigraphic position and association, see p. 133.) Middle Cambrian: In the shaly sandstones of Division E3a of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Obolus (Palaeobolus) bretonensis. | Acrothele avia.
Lingulella atava. | Acrothele proles.

Matthew [1903] cites the following from this locality:

Obolus lens (pp. 58, 80). | Acrothele abavia.
Obolus (Palaeobolus) bretonensis (p. 26). | Acrothyra proavia (p. 57).
Lingula sp. | *Acrothyra proavia prima.
Leptobolus sp.

Bassler cites the following from this locality:

Bradoria acuta (Matthew).
Bradoria curta Bassler.

13m. (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstones of Division E3f of Matthew's [1903, p. 76] Etcheminian, on Gillis Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Obolus (Palaeobolus) bretonensis lens. | Acrothele avia.
Lingulella collicia. | *Acrothele proles.

Matthew [1903] cites the following:

Leptobolus collicia=Lingulella collicia. | Acrothyra proavia crassa=Acrothyra proavia.
Leptobolus collicia collis=Lingulella collicia. | Acrothyra proavia prima=Acrothyra proavia.
Acrothele avia puteis. | Leperditia?? rugosa.
Acrothele proles. | Bradoria scrutator.

Bassler cites the following from locality No. 13m'':

Bradoria acuta (Matthew).
Bradoria vigilans Matthew.
Beyrichona rutellum (Matthew).

13n (see 344d). (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstones of Division E3f of Matthew's [1903, p. 21] Etcheminian, on Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella atava.
Acrothele avia.
Acrothele proles.

Matthew [1903, p. 37] cites the following:

Leptobolus atavus=Lingulella atava. | Acrothyra proavia prima?=Acrothyra proavia.
Leptobolus collicia=Lingulella collicia. | Bradorona perspicator major.
Leptobolus collicia collis=Lingulella collicia. | Bradorona scrutator.
Acrothele proles. | Solenopleura (?) bretonensis (part).
Acrothyra crassa?=Acrothyra proavia.

Bassler cites the following:

Bradoria scrutator (Matthew).
Indiana lippa (Matthew).
Walcottella fusiformis (Matthew).

13n'. (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstones of Division E3e of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

*Obolus (Palaeobolus) bretonensis lens. | *Lingulella tumida.
*Lingulella atava. | *Acrothele avia.
*Lingulella collicia. | Acrothyra proavia.

Matthew [1903, p. 27] cites the following:

Obolus lens. | Acrothyra proavia crassa.
Obolus lens longus. | Indiana ovalis.
Lingulella tumida. | Bradorona observator ligata.
Lingulella sp. | Bradorona scrutator.
Leptobolus atavus. | Bradoria rugulosa.
Leptobolus collicia. | Bradoria vigilans.
Acrothele abavia. | Schmidtella? acuta.
Acrothele avia. | Schmidtella? pervetus.
Acrothyra proavia.

Bassler cites the following:

Indiana lippa (Matthew).
 Bradoria robusta (Matthew).
 Bradoria rugulosa Matthew.
 Bradoria scrutator (Matthew).

Bradoria vigilans Matthew
 Bradoria ovalis Matthew.
 Bradoria acuta (Matthew).

13n'' (see 344b). (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandstones of Division E3d of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, Cape Breton, Nova Scotia (S. W. Loper, 1903).

Obolus (Palæobolus) bretonensis.
 Lingulella atava.
 Acrothyra proavia.

Matthew [1903, p. 26] cites the following:

Obolus bretonensis.
 Leptobolus atavus.

Acrothele avia.
 Bradorona spectator æquat.

Bassler cites the following:

Bradoria acuta (Matthew).
 Bradoria elongata n. sp.
 Bradoria obesa (Matthew).

Bradoria robusta (Matthew).
 Bradoria vigilans Matthew.

13p (see 13g, 13f, 13d'', and 13p'). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones 40 feet (12.2 m.) above Division E2a of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella (Lingulepis) longinervis.
 Acrothyra sera?.

13p' (see 13p, 13g, 13f, and 13d''). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstone 45 feet (13.6 m.) above Division E2a of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella (Lingulepis) longinervis.
 Acrothyra sera?.

13q. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales of the "Bretonian" division of Matthew's [1903, p. 45] section on Gillis Brook, East Bay, Cape Breton, Nova Scotia (S. W. Loper, 1903).

Ornsia lenticularis.
 Bradoria robusta (Matthew).

13r (little different horizon from 13i). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstone of the "Johannian" division of Matthew's section on Gillis Brook, East Bay, east of Bras d'Or Lake, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella tumida.
 Lingulella (Lingulepis) exigua.

13t. (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones at the base of Division E1b of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

*Lingulella triparilis.
 Lingulella tumida.

Acrothele prima.
 Acrothyra signata.

Bassler cites the following:

Bradoria rugulosa Matthew (emend.).
 Bradoria robusta (Matthew).
 Bradoria robusta n. var.

13t' (same locality as 10p; see 344k). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones of Division E1b of Matthew's [1903, p. 21] Etcheminian, Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella triparilis.

13t'' (see 344m). (For stratigraphic position and association, see p. 134.) Middle Cambrian: Sandstones of Divisions E1c and E1d of Matthew's [1903, p. 21] Etcheminian, on Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).

Lingulella triparilis.
 Lingulella (Lingulepis) gregwa.
 Acrothyra sera.

Acrothyra signata.
 Bradoria robusta (Matthew).
 Bradoria concinna (Matthew).

Matthew [1903] cites the following as occurring in 1d:

| | |
|-----------------------------------------|------------------------------------------|
| Lingulepis gregwa. | Bradorona observator Matthew. |
| Lingulepis gregwa robusta. | Bradorona observator benepuncta Matthew. |
| Acrotreta papillata=Acrothyra sera. | Bradorona perspicator Matthew. |
| Acrotreta signata tarda=Acrothyra sera. | Bradorona spectator Matthew. |
| Orthotheca sp. | Bradorona spectator acuta Matthew. |

14. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestones overlying the sandstones of the Rome formation, near the wagon road and in a quarry near the railroad track, 7 miles (11.2 km.) southwest of Rome [see Hayes, 1902, historical geology sheet], Floyd County, Ga. (C. D. Walcott, 1891).

Micromitra (Iphidella) pannula.
Billingsella appalachia?
Dorypyge?.

- 14a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandstone of the Rome formation, along First Creek Gap, 4 miles (6.4 km.) north-northeast of Knoxville [Keith, 1905, areal geology sheet], Knox County, Tenn. (M. R. Campbell, 1891).

| | |
|--------------------------|----------------------|
| Micromitra alabamaensis. | Lingulella similis. |
| Obolus willisi. | *Wimanella saffordi. |
| Obolus (Westonia) ella. | |

- 14b. Upper Cambrian: Limestone on Cold Creek, at north end of gorge opposite the north end of Sponge Mountain, 2 miles (3.2 km.) south of the San Saba County line, in Llano County, Tex. (J. A. Taff, E. O. Ulrich, and J. W. Beede).

| | |
|------------------------------------|-------------------------------------|
| Obolus matinalis. | Acrotreta microscopica. |
| *Obolus nundina. | Billingsella coloradoensis. |
| Obolus sinoe. | Eoorthis indianola?. |
| Lingulella acutangula. | Eoorthis remnicha texana. |
| Lingulella upis. | Eoorthis wichitaensis. |
| Lingulella (Lingulepis) acuminata. | Eoorthis wichitaensis laeviusculus. |

- 14c. Upper Cambrian: Upper part of the limestone exposed at Baldwin's ranch, on Cold Creek, 2.5 miles (4 km.) south of the San Saba County line, in Llano County, Tex. (E. O. Ulrich).

Obolus matinalis.

- 14e (see 14q). Upper Cambrian: Limestone in Bartlett Hollow, 2 miles (3.2 km.) southeast of the mouth of Falls Creek, Burnet quadrangle (U. S. G. S.), Lampasas County, Tex. (Bailey Willis, E. O. Ulrich, and J. A. Taff).

Obolus matinalis.
Obolus sinoe.
Acrotreta microscopica.

- 14g (=14i). (E. O. Ulrich, J. A. Taff, and J. W. Beede.)

Lingulella upis.
Acrotreta microscopica.
Billingsella coloradoensis.

- 14i (=14g). Upper Cambrian: Upper part of limestone exposed 1 mile (1.6 km.) west of Cherokee, San Saba County, Tex. (E. O. Ulrich, J. A. Taff, and J. W. Beede).

Lingulella acutangula.
*Lingulella upis.
Linnarssonella girtyi.

- 14k. Upper Cambrian: Limestone on Wolf Creek, 15 miles (24.2 km.) west-southwest of Sheridan, Bighorn Mountains, Sheridan County, Wyo.

Eoorthis desmopleura.
*Syntrophia rotundata.

- 14l. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Sandstones about 2,800 feet (853 m.) below the Middle Cambrian, in a horizon correlated with No. 2j of the Silver Peak group of the Waucoba Springs section [Walcott, 1908f, p. 187], in the pass about 7 miles (11.2 km.) east of Resting (Freshwater) Springs, which is in the southwest corner of T. 21 N., R. 8 E., on Amargosa River, in the southeastern part of Inyo County, Cal. (R. B. Rowe, 1901).

*Billingsella bivia.
Olenellus fremonti Walcott

- 14m.** (For stratigraphic position and association, see p. 140.) Middle Cambrian: Limestone about 7 miles (11.2 km.) south of Towner's ranch, Indian Creek, Lincoln County, Nev. (R. B. Rowe, 1901).
Lingulella arguta.
- 14n.** Middle Cambrian: Limestone about 310 feet (94.5 m.) above the Lower Cambrian, on the east side of the pass about 7 miles (11.2 km.) east of Resting (Freshwater) Springs, which is the southwest corner of T. 21 N., R. 8 E., on Amargosa River, in the southeastern part of Inyo County, Cal. (R. B. Rowe, 1901).
Obolus mcconnelli.
Obolus mcconnelli decipiens.
- 14o.** (For stratigraphic position and association, see p. 138.) Lower Cambrian: Sandstones about 3,500 feet (1,067 m.) below the Middle Cambrian, in the pass about 7 miles (11.2 km.) east of Resting (Freshwater) Springs, which is the southwest corner of T. 21 N., R. 8 E., on Amargosa River, in the southeastern part of Inyo County, Cal. (R. B. Rowe, 1901).
Obolella sp. undt.
- 14p.** (For stratigraphic position and association, see p. 138.) Lower Cambrian: Reddish-brown quartzitic sandstone near Resting (Freshwater) Springs, which is in the southwest corner of T. 21 N., R. 8 E., on Amargosa River, in the southeastern part of Inyo County, Cal. (M. R. Campbell and R. B. Rowe, 1901).
*Lingulella (Lingulepis) rowei. | Wanneria gracile Walcott.
Obolella vermilionensis. | Olenellus fremonti Walcott.
Billingsella bivia. | Cystid plate.
- 14q** (see 14e). Upper Cambrian: Sandstone in Bartlett Hollow, 1.5 miles (2.4 km.) southeast of the mouth of Falls Creek, Burnet quadrangle (U. S. G. S.), Lampasas County, Tex. (E. O. Ulrich).
Obolus matinalis.
- 14r.** Upper Cambrian: Sandstone in the lower part of the beds exposed on Colorado River, 3 miles (4.8 km.) south of the northeast corner of Llano County, Tex. (E. O. Ulrich).
Obolus matinalis.
Lingulella (Lingulepis) acuminata.
- 14s.** (For stratigraphic position and association, see p. 127.) Middle Cambrian: About 2,300 feet (701 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian, in the *Ogygopsis* zone of the Stephen formation [Walcott, 1908f, p. 210], at the great "fossil bed" on the northwest slope of Mount Stephen, above Field on the Canadian Pacific Railway, British Columbia, Canada (W. D. Wilcox, 1894; Mr. and Mrs. C. D. Walcott and Mr. and Mrs. L. D. Burling, 1907).
Micromitra (Iphidella) pannula. | Anomalocaris canadensis Whiteaves.
Micromitra (Iphidella) pannula ophirensis. | Anomalocaris? whiteavesi Walcott.
*Obolus mcconnelli. | Agnostus montis Matthew.
*Obolus septalis. | Dorypyge (Kootenia) dawsoni (Walcott).
Acrothele colleni. | Bathyriscus occidentalis (Matthew).
*Acrotreta depressa. | Bathyriscus ornatus Walcott.
*Philhedra columbiana. | Bathyriscus pupa Matthew.
*Nisusia alberta. | Bathyriscus rotundatus (Rominger).
Hyalithellus annulatus (Matthew). | Karlia stephenensis Walcott.
Hyalithellus flagellum (Matthew). | Neolenus granulatus Matthew = Neolenus serratus.
Orthotheca corrugata Matthew. | Neolenus serratus (Rominger).
Orthotheca major Walcott. | Ogygopsis klotzi (Rominger).
Hyalithes carinatus Matthew. | Oryctocephalus reynoldsi Reed.
Hyalithes sp. | Oryctocephalus walkeri Matthew = Oryctocephalus reynoldsi.
Stenotheca wheeleri Walcott. | Burlingia hectori Walcott.
Platyceras bellianus Walcott. | Ptychoparia cordilleræ (Rominger).
Platyceras romingeri Walcott. | Ptychoparia palliseri Walcott.
Scenella varians Walcott. | Zacanthoides spinosus (Walcott).
Anomalocaris?? acutangula Walcott.
- 14t.** (For stratigraphic position and association, see p. 157.) Middle Cambrian: Limestone lying on slope between the Cambrian quartzite and the massive blue limestone 100 feet (30.5 m.) above, Mount Nebo Canyon, 3 miles (4.8 km.) southeast of Mona, Juab County, Utah (F. B. Weeks, 1903).
Micromitra (Iphidella) pannula.
Lingulella cf. similis.
*Acrotreta neboensis.

- 14v. (For stratigraphic position and association, see p. 156.) Middle Cambrian: Shales of unknown stratigraphic horizon collected 1 mile (1.6 km.) south of Rainbow Valley, House Range [see Walcott, 1908f, Pl. XIII], Millard County, Utah.
Obolus mcconnelli.
- 14x. Middle Cambrian: About 400 feet (122 m.) above the bottom of Tombstone Gulch, in the Abrigo limestone [Ransome, 1904, p. 3], in the northwest suburb of Bisbee [see Ransome, 1904, areal geology sheet], Cochise County, Ariz. (F. L. Ransome, 1903).
Obolus tetonensis.
Billingsella??.
- 15b. (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 1,700 feet (518.2 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian, in the shaly limestones and calcareous shales of the Wheeler formation [Walcott, 1908f, p. 181], near Swasey Spring, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (G. K. Gilbert, 1903).
Acrothele subsidua.
- 15e. (For stratigraphic position and association, see p. 156.) Middle Cambrian: Marjum limestone [Walcott, 1908a, p. 10], near Swasey Spring, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (G. K. Gilbert, 1901).
Nisusia (Jamesella) nautes?.
Anomocare sp.
- 15d (same horizon as 33d). (For stratigraphic position and association, see p. 154.) Upper Cambrian: Thin-bedded blue limestone near Cave Spring, on the east side of the Fish Spring Range, about 4 miles (6.4 km.) south of the J. J. Thomas ranch, Juab County, Utah (G. K. Gilbert, 1901).
Lingulella desiderata.
 **Lingulella isse*.
Lingulella manticula.

- 16j. (For stratigraphic position and association, see p. 145.) Middle Cambrian: Limestones of *Paradoxides forchhammeri* zone at Laesaå, Bornholm Island, Denmark (K. A. Grönwall, 1903).
 Micromitra pusilla. | Acrotreta sagittalis.
 Lingulella ferruginea. | Acrotreta schmalenseei.
 Acrothele coriacea.
- 16k. (For stratigraphic position and association, see p. 146.) Middle Cambrian: Limestones of *Paradoxides davidis* zone at Laesaå, Bornholm Island, Denmark (K. A. Grönwall, 1903).
 Acrothele coriacea.
 Acrotreta sagittalis.
- 16l. (For stratigraphic position and association, see p. 146.) Middle Cambrian: Limestones of *Paradoxides davidis* zone at Borregaard, Bornholm Island, Denmark (K. A. Grönwall, 1903).
 Acrothele coriacea.
 Acrotreta sagittalis.
- 16n. Upper Cambrian: Interformational conglomerate and shales in Adams pasture, 0.5 mile (0.8 km.) west of Main Street, on Lake Street, St. Albans, Franklin County, Vt. (Geo. H. Edson; H. E. Dickhaut, 1903).
 Lingulella?
 Lingulella (*Lingulepis*) acuminata.
 Yorkia sp.
- 16o. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales on McMullins Brook, in the East Boisdale district, eastern Cape Breton, Nova Scotia (S. W. Loper, 1903).
 Lingulella concinna.
- 17b. (For stratigraphic position and association, see p. 147.) Lower Cambrian: Rome ("Montevallo") formation 4 miles (6.4 km.) south of Helena, Shelby County, Ala. (C. D. Walcott, 1895).
 Micromitra (*Paterina*) major. | *Obolus smithi*.
 Micromitra (*Paterina*) williardi. | **Wimanella shelbyensis*.
- 17c. Middle Cambrian: Sandy limestone 235 feet (71.6 m.) above the "Tonto" sandstone, Grand View trail north of Last Chance copper mine, south side of the Grand Canyon of the Colorado, Arizona.
 **Obolus* (*Westonia*) *themis*.
 Lingulella acutangula.
 Lingulella lineolata.
- 17j. Middle Cambrian: Limestone in the east end of the town of Galena, Black Hills, South Dakota.
 Lingulella similis.
- 17k. Middle Cambrian: Limestone thrown out on the dump of the Great Northern shaft, southeast of Twobit, northern Black Hills, Lawrence County, South Dakota.
 Linnarssonella girtyi.
18. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone 1 mile (1.6 km.) east of Gap Creek, 13 miles (20.8 km.) S. 75° E. of Knoxville, Knox County, Tenn. (A. Keith and C. D. Walcott).
 Acrotreta kutorgai?.
- 20 (see 21a). Lower Cambrian: Limestone on the south side of Mettawee River, 0.25 mile (0.4 km.) above the North Granville bridge, Fort Ann quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1890).
 Obolella crassa.
 Medusa? sp.
- 20a. Lower Cambrian: Gray limestone interbedded with shaly slates in a lane west of Lafayette Stevens's house, about 100 yards (91.4 m.) from the main road in the southern part of Whitehall township, Fort Ann quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1890).
 Lingulella granvillensis. | *Olenellus*?
 Acrotreta sagittalis taconica. | *Olenoides fordi* Walcott.
 Hyolithellus micans (*Billings*). | *Ptychoparia* sp.
 Microdiscus connexus Walcott.
21. Lower Cambrian: Shales 1.5 miles (2.4 km.) south of Salem, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1890).
 Billingsella salemensis. | *Microdiscus lobatus* (Hall).
 Archæocyathus dwighti Walcott. | *Olenellus*.
 Stenotheca rugosa (Hall). | *Solenopleura? tumida* Walcott.
 Fordilla troyensis Barrande. | *Leperditia? dermatoides* (Walcott).

- 21a. Lower Cambrian: Limestone below the first fall of Mettawee River, above the North Granville bridge, Fort Ann quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1890).
Lingulella granvillensis. | *Olenellus?*
Microdiscus connexus Walcott. | *Ptychoparia* sp.
22. Lower Cambrian: Limestone 1.5 miles (2.4 km.) north of North Granville, Fort Ann quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1891).
Acrothele nitida. | *Microdiscus lobatus* (Hall).
Acrotreta sagittalis taconica. | *Olenellus*.
Hyalithellus micans (Billings).
- 22a. Lower Cambrian: Limestone in Penrhyn quarries, Middle Granville, Mettawee quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1890).
Lingulella sp.
Acrotreta sagittalis taconica.
Billingsella salemensis.
25. Lower Cambrian: Sandstone just above Parker's quarry, near Georgia, Franklin County, Vt. (C. D. Walcott and Cooper Curtice, 1883).
**Rustella edsoni*. | **Olenellus thompsoni* (Hall).
Micromitra (Paterina) bella. | *Olenellus thompsoni crassimarginatus* Walcott.
Nisusia festinata. | *Microdiscus parkeri* Walcott.
**Nisusia festinata transversa*. | *Ptychoparia adamsi* (Billings).
Medusa? sp. | *Ptychoparia vulcanus* (Billings).
Eocystites? sp. | *Protypus senectus* (Billings).
**Mesonacis vermontana* (Hall). | *Bathynotus holopyga* (Hall).
**Pædeumias transitans* Walcott. | *Olenoides marcoui* (Whitfield).
- 25a. Lower Cambrian: Limestone on the Hall (Donaldson's) farm, 2 miles (3.2 km.) east of Swanton, Franklin County, Vt. (C. D. Walcott and Cooper Curtice, 1883).
**Micromitra (Paterina) labradorica swantonensis*. | *Billingsella orientalis*.
Obolus cf. prindlei. | *Hyalithes* sp.
Lingulella granvillensis. | *Salterella pulchella* Billings.
Kutorgina cingulata. | *Olenellus thompsoni* (Hall).
Nisusia festinata. | *Ptychoparia adamsi* (Billings).
Nisusia festinata transversa. | *Protypus senectus* (Billings).
26. Lower Cambrian: Sandstone northeast of the Corman farm buildings, east of Highgate Springs, Franklin County, Vt. (C. D. Walcott and Cooper Curtice, 1883).
Micromitra (Paterina) labradorica swantonensis. | *Olenoides desiderata* (Walcott).
Nisusia festinata. | *Ptychoparia adamsi* (Billings).
Billingsella orientalis. | *Ptychoparia teucer* (Billings).
Scenella varians Walcott. | *Ptychoparia vulcanus* (Billings).
Hyalithes sp. | *Ptychoparia* sp.
27. Lower Cambrian: Even-bedded and conglomerate limestones on the ridge in the eastern suburb of Troy, Troy quadrangle (U. S. G. S.), Rensselaer County, N. Y. (Cooper Curtice, 1883).
Obolella crassa. | *Hyalithes americanus* Billings.
Bicia gemma. | *Hyalithes communis* Billings.
Botsfordia cælata. | *Hyalithes communis emmonsii* Ford.
**Acrothele nitida*. | *Hyalithes impar* Ford.
Archæocyathus rarus (Ford). | *Hyalithes* sp.
Archæocyathus rensselaericum (Ford). | *Microdiscus lobatus* (Hall).
Scenella retusa Ford. | *Microdiscus speciosus* Ford.
Stenotheca rugosa (Hall). | *Elliptocephala asaphoides* Emmons.
Platyceras primævum Billings. | *Olenoides fordii* Walcott.
Hyalithellus micans Billings. | *Solenopleura nana* Ford.
- 27a. Lower Cambrian: Reddish sandstone about 1 mile (1.6 km.) east of Lansingburg, north of Troy, Cohoes quadrangle (U. S. G. S.), Rensselaer County, N. Y. (Cooper Curtice, 1883).
Obolella crassa.

28. Upper Cambrian: Shales about 100 feet (30.5 m.) above the *Olenellus* horizon, south of Highgate Falls, 0.25 mile (0.4 km.) east of Swanton, Franklin County, Vt. (C. D. Walcott, 1884).

**Protorthis wingi*.

Hyalolithes sp.

Ptychoparia adamsi (Billings.)

- 28a. Middle? Cambrian: "St. Albans formation," in limestone lentile about 1 mile (1.6 km.) east of Parker's quarry, near Georgia, Franklin County, Vt. (C. D. Walcott, 1884).

Lingulella franklinensis.

**Huenella billingsi*.

Ptychoparia adamsi (Billings.)

- 29 (see 338b). Lower Cambrian: Limestone just above the bridge at the Stockport paper mill, on Kinderhook Creek, Columbia County, N. Y. (C. D. Walcott and S. W. Ford).

Obolus prindlei.

Lingulella granvillensis.

Acrotreta sagittalis taconica.

- 29a (see 338). Lower Cambrian: Limestone 1 mile (1.6 km.) below the New York Central Railroad depot at Schodack Landing, Rensselaer County, N. Y. (C. D. Walcott and S. W. Ford).

Obolella crassa.

Botsfordia caelata.

Bicia gemma.

Acrotreta sagittalis taconica.

Hyalithellus micans (Billings.)

Hyalolithes americanus Billings.

Microdiscus lobatus (Hall).

Microdiscus speciosus Ford.

Elliptocephala asaphoides Emmons.

30. (For stratigraphic position and association, see p. 158.) Lower Cambrian: Limestone 8 miles (12.8 km.) north of Bennetts Spring, on the west slope of the Highland Range, Lincoln County, Nev. (C. D. Walcott and J. E. W., 1885).

Micromitra (*Iphidella*) *pannula*.

Obolus (*Westonia*) *ella*.

Billingsella highlandensis.

Callavia nevadensis Walcott.

Olenellus fremonti Walcott.

Olenellus gilberti (Meek).

Peachella iddingsi Walcott.

Sponge?.

Crepicephalus augusta Walcott.

Crepicephalus liliana Walcott.

- 30a. (For stratigraphic position and association, see p. 158.) Middle Cambrian: Shale on north side of Big Cottonwood Canyon, 1 mile (1.6 km.) below Argenta, in the Wasatch Mountains, southeast of Salt Lake City, Salt Lake County, Utah (C. D. Walcott and J. E. W., 1885).

Micromitra (*Iphidella*) *pannula*.

Obolus (*Westonia*) *ella*.

Lingulella helena.

Hyalithellus sp.

Hyalolithes billingsi Walcott.

Walcott [1886] wrongly includes *Cruziana* and *Olenellus gilberti* in this fauna (see Walcott, 1891b, p. 319).

Isoxys argentea (Walcott).

Ptychoparia quadrans (Hall and Whitfield).

Bathyriscus productus (Hall and Whitfield).

Olenoides wasatchensis (Hall and Whitfield).

- 30c (=11w). (For stratigraphic position and association, see p. 157.) (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905.)

Micromitra (*Paterina*) *labradorica utahensis*.

Ptychoparia 2 sp.

- 30d. (For stratigraphic position and association, see p. 157.) Middle Cambrian: About 1,020 feet (310.9 m.) above the Lower Cambrian and 3,400 feet (1,036.3 m.) below the Upper Cambrian, in the limestone forming 1e of the Swasey formation [Walcott, 1908f, p. 182], at the head of Dome Canyon, about 2 miles (3.2 km.) west-southwest of Antelope Springs, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (F. B. Weeks, 1905).

Obolus (*Westonia*) *ella*.

Ptychoparia, several species.

- 30e. (For stratigraphic position and association, see p. 158.) Middle Cambrian: About 100 feet (30.5 m.) above the Lower Cambrian and 4,300 feet (1,310.6 m.) below the Upper Cambrian, in the limestones forming 1a of the Langston (?) limestone [Walcott, 1908f, p. 183], in Dome Canyon, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).

Billingsella sp. undt.

Hyalolithes.

Leperditia?

Zacanthoides.

Ptychoparia.

Dorypyge?

- 30g** (=11q and 11y; same horizon as 3w). (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 2,350 feet (716.3 m.) above the Lower Cambrian and 2,050 feet (624.8 m.) below the Upper Cambrian, in the limestone forming 1c of the Marjum limestone [Walcott, 1908f, p. 180], 2.5 miles (4 km.) east of Antelope Springs, in ridge east of Wheeler Amphitheater [Walcott, 1908f, Pls. XIII and XV], House Range, Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).

30o (=14v). (For stratigraphic position and association, see p. 154.) Middle Cambrian: About 3,950 feet (1,204 m.) above the Lower Cambrian and 450 feet (137.2 m.) below the Upper Cambrian, in the shaly limestones forming 1b of the Weeks limestone [Walcott, 1908f, p. 178], on the north side of Weeks Canyon, about 4 miles (6.4 km.) south of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (C. D. Walcott and L. D. Burling, 1905).

Obolus (*Fordinia*) *perfectus*.

Asaphiscus sp.

Agnostus, several species.

Ptychoparia.

Crepicephalus texanus (Shumard).

Bathyuriscus.

Anomocare?

Solenopleura.

30p. (For stratigraphic position and association, see p. 151.) Middle Cambrian: About 125 feet (38 m.) above the Cambrian quartzitic sandstones on the north side of Ogden Canyon, about 1 mile (1.6 km.) above its mouth, east of Ogden, Weber County, Utah (F. B. Weeks and L. D. Burling, 1905).

Micromitra (*Paterina*) *labradorica utahensis*.

Obolus mcconnelli.

Obolus (*Westonia*) *ella*.

30q. (For stratigraphic position and association, see p. 149.) Upper Cambrian: Limestones about 2,300 feet (701 m.) above the Cambrian quartzitic sandstones on pipe line above limekiln in Ogden Canyon, 1 mile (1.6 km.) above its mouth, east of Ogden, Weber County, Utah (F. B. Weeks and L. D. Burling, 1905).

Obolus rotundatus.

Lingulella manticula.

30s. (For stratigraphic position and association, see p. 149.) Upper Cambrian: Green shale about 1,200 feet (365.8 m.) above the Cambrian quartzitic sandstones on pipe line above limekiln in Ogden Canyon, 1 mile (1.6 km.) above its mouth, east of Ogden, Weber County, Utah (L. D. Burling, 1905).

Lingulella isse.

30u. (For stratigraphic position and association, see p. 151.) Middle Cambrian: Sandy shales about 250 feet (76.2 m.) above the top of the Cambrian quartzitic sandstones 4 miles (6.4 km.) northwest of Promontory Point station (on the "Lucin cut-off" of the Union Pacific Railway), about halfway up west end of ridge, north of Great Salt Lake, Boxelder County, Utah (F. B. Weeks, 1905).

Micromitra (*Paterina*) *labradorica utahensis*.

Acrotreta cf. *ophirensis*.

30w. (For stratigraphic position and association, see p. 153.) Upper Cambrian: Drift boulder of limestone supposed to have come from the beds forming 1a of the Notch Peak limestone on Notch Peak [Walcott, 1908f, p. 175], found about 2 miles (3.2 km.) south of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (C. D. Walcott and F. B. Weeks, 1905).

Schizambon typicalis.

Eoorthis desmopleura.

Agraulos.

Solenopleura.

Illænenurus.

30y (the metamorphosed equivalent of 301 at a different locality). (For stratigraphic position and association, see p. 153.) Upper Cambrian: About 1,400 feet (426.7 m.) above the Middle Cambrian and 1,900 feet (579.1 m.) below the top of the Upper Cambrian, in the supposed metamorphosed equivalent of the shales forming 1b of the Orr formation [Walcott, 1908f, p. 176], above the grauwacke contact on top of the ridge north of Notch Peak [Walcott, 1908f, Pls. XIII and XIV], House Range, Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).

Obolus rotundatus.

Lingulella isse.

Anomocare.

30z. (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 2,450 feet (746.8 m.) above the Lower Cambrian and 1,950 feet (594.4 m.) below the Upper Cambrian, in the upper part of the limestone forming 1c of the Marjum limestone [Walcott, 1908f, p. 180], in the long cliff about 2 miles (3.2 km.) south-east of Marjum Pass, House Range [Walcott, 1908f, Pls. XIII and XV], Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).

Acrotreta pyxidicula.

Agnostus.

Ptychoparia.

31. (For stratigraphic position and association, see p. 158.) Middle Cambrian: Shales at the Chisholm mine, southwest slope of Ely Mountains, 3 miles (4.8 km.) northwest of Pioche, Lincoln County, Nev. (C. D. Walcott and J. E. W., 1885).

Obolus (Westonia) ella.

Acrothele spurri.

Acrotreta cf. ophirensis.

Scenella.

Hyalolithes.

Zacanthoides.

Bathyuriscus.

- 31t** (25 feet above 30k at same locality). (For stratigraphic position and association, see p. 154.) Upper Cambrian: About 1,175 feet (358.1 m.) above the Middle Cambrian and 2,150 feet (655.3 m.) below the top of the Upper Cambrian, in the limestone forming Id of the Orr formation [Walcott, 1908f, p. 176], on Orr Ridge, about 5 miles (8 km.) south of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah (L. D. Burling, 1905).

Linnarssonella modesta.

**Linnarssonella nitens.*

Solenopleura.

Protaspis.

- 31u.** (For stratigraphic position and association, see p. 158.) Middle Cambrian: Shales on west slope of spur facing the main part of the Highland Range, 3 miles (4.8 km.) northwest of Pioche, Lincoln County, Nev.

Walcott [1891b, p. 318] cites the following species from this locality:

Lingulella ella=*Obolus (Westonia) ella.*

Kutorgina pannula=*Micromitra (Iphidella) pannula.*

Eocystites?? longidactylus Walcott.

Hyalolithes billingsi Walcott.

Ptychoparia piochensis Walcott.

Zacanthoides typicalis (Walcott).

Bathyuriscus howelli Walcott.

Bathyuriscus productus (Hall and Whitfield).

- 31v.** (For stratigraphic position and association, see p. 157.) Middle Cambrian: 650 feet (198.1 m.) above the Lower Cambrian and 3,750 feet (1,143 m.) below the Upper Cambrian, in shales at the top of the limestone forming Ia of the Howell formation [Walcott, 1908f, p. 182], northeast side of Dome Canyon, about 4 miles (6.4 km.) west-southwest of Antelope Springs, House Range [Walcott, 1908f, Pls. XIII and XVI], Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).

Micromitra (Iphidella) pannula.

Acrotreta cf. ophirensis.

Ptychoparia.

- 31y.** (For stratigraphic position and association, see p. 151.) Middle Cambrian: Thin-bedded limestone about 125 feet (38 m.) above the Cambrian quartzitic sandstones in the Wasatch Mountains, 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County, Utah (F. B. Weeks and L. D. Burling, 1905).

Obolus mcconnelli.

Lingulella isse.

- 31z** (=55t). (For stratigraphic position and association, see p. 151.) Middle Cambrian: About 350 feet (106.7 m.) above the Brigham quartzite, in the limestone of the Ute limestone [Walcott, 1908a, p. 7], on west side of road, 0.5 mile (0.8 km.) above the forks, Paradise Dry Canyon (locally known as East Fork), east of Paradise, Cache County, Utah (F. B. Weeks, 1905).

Otusia utahensis.

Acrotreta ophirensis.

- 32.** Lower Cambrian: Sandstone on the south slope of Stissing Mountain, Dutchess County, N. Y. (C. D. Walcott, 1886).

**Obolella minor.*

Obolella sp.

Elliptocephala asaphoides Emmons.

- 32a.** Lower Cambrian: Limestone, 0.75 mile (1.2 km.) west of Riders Mill station on the Harlem Extension Railroad, about 9 miles (14.4 km.) north-northeast of Chatham, Kinderhook quadrangle (U. S. G. S.), Columbia County, N. Y. (C. D. Walcott and T. N. Dale, 1891).

Bicia gemma.

Acrotreta sagittalis taconica.

- 32e. (For stratigraphic position and association, see p. 152.) Middle Cambrian: About 60 feet (18.3 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in green shale 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County, Utah (L. D. Burling, 1905).
Acrotreta cf. ophirensis.
- 32d. (For stratigraphic position and association, see p. 152.) Middle Cambrian: Shales about 150 feet (45.7 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], on the east side of the south fork of Paradise Dry Canyon (locally known as East Fork), east of Paradise, Cache County, Utah (F. B. Weeks, 1905).
Micromitra (Paterina) labradorica utahensis.
Obolus (Westonia) ella.
- 32e (same horizon as 31c and 54o). (For stratigraphic position and association, see p. 151.) Middle Cambrian: About 900 feet (274.3 m.) above the Brigham quartzite and 3,300 feet (1,005.8 m.) below the Upper Cambrian, in limestone corresponding to that forming 1b of the Ute limestone [Walcott, 1908f, p. 196], just south of the south fork of Paradise Dry Canyon (locally known as East Fork), east of Paradise, Cache County, Utah (L. D. Burling, 1905).
Otusia utahensis.
*Syntrophia cambria.
- 32f. (For stratigraphic position and association, see p. 153.) Upper Cambrian: Thin-bedded siliceous limestone near the top of the Upper Cambrian, about 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah (F. B. Weeks and L. D. Burling, 1905).
Lingulella manticula.
Lingulella pogonipensis.
- 32g. (For stratigraphic position and association, see p. 154.) Upper Cambrian: About 2,575 feet (784.9 m.) above the Cambrian quartzitic sandstones, in a blue limestone about 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah (L. D. Burling, 1905).
Obolus mcconnelli pelias. | Lingulella isse.
Lingulella desiderata. | Linnarssonella nitens.
- 32h. (For stratigraphic position and association, see p. 157.) Middle Cambrian: Shales in a canyon on the west side of the Simpson Range, 4 miles (6.4 km.) south of Simpson Spring, about 20 miles (32.2 km.) west-southwest of Vernon, Tooele County, Utah (F. B. Weeks and L. D. Burling, 1905).
Obolus (Westonia) ella.
- 32j. (For stratigraphic position and association, see p. 157.) Middle Cambrian: 625 feet (190.5 m.) above the Cambrian quartzitic sandstones, in pinkish-colored very fine grained arenaceous shale 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah (L. D. Burling, 1905).
Acrotreta cf. ophirensis.
- 32k. (For stratigraphic position and association, see p. 156.) Middle? Cambrian: Limestones about 1,550 feet (472.4 m.) above the top of the Cambrian quartzitic sandstones 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah (L. D. Burling, 1905).
Obolus mcconnelli.
- 32n. (For stratigraphic position and association, see p. 151.) Middle Cambrian: Shales about 725 feet (221 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in the Wasatch Mountains, 1 mile (1.6 km.) northwest of Geneva (Copenhagen), Boxelder County, Utah (L. D. Burling, 1905).
Obolus (Westonia) ella?.
- 32o. (For stratigraphic position and association, see p. 158.) Middle Cambrian: Shale about 325 feet (99 m.) above the Cambrian quartzitic sandstones 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah (L. D. Burling, 1905).
Obolus (Westonia) ella.
- 32p (=55e). (For stratigraphic position and association, see p. 152.) (L. D. Burling, 1905).
Obolus (Westonia) ella.
Acrothele subsidua.
- 32t. (For stratigraphic position and association, see p. 154.) Upper Cambrian: Limestone about 3,650 feet (1,112.5 m.) above the Cambrian quartzitic sandstones in Fandango Spring canyon, on the east side of the Dugway Range, about 5 miles (8 km.) north of where the stage road between Vernon and Deep Creek crosses the divide, Tooele County, Utah (L. D. Burling, 1905).
Linnarssonella girtyi.

32x (=54k faunally). (For stratigraphic position and association, see p. 150.) Middle Cambrian: About 1,700 feet (518.2 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in shales correlated with the shales forming 2d of the Bloomington formation in Blacksmith Fork Canyon [Walcott, 1908f, p. 195], Wasatch Canyon, east of Lakeview ranch, 5 miles (8 km.) north of Brigham, Boxelder County, Utah (L. D. Burling, 1905).
Obolus (*Westonia*) *wasatchensis*.

32y. (For stratigraphic position and association, see p. 151.) Middle Cambrian: Shales about 175 feet (53.3 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in the Wasatch Mountains, 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County, Utah (F. B. Weeks and L. D. Burling, 1905).
Obolus (*Westonia*) *ella*.

32z (below 32h at same locality). (For stratigraphic position and association, see p. 157.) Middle Cambrian: Shales in a canyon on the west side of the Simpson Range, 4 miles (6.4 km.) south of Simpson Spring, about 20 miles (32.2 km.) west-southwest of Vernon, Tooele County, Utah (F. B. Weeks and L. D. Burling, 1905).
Obolus (*Westonia*) *ella*.

33 (see 338c). Lower Cambrian: Limestone on the roadside near Rock Hill schoolhouse, near North Greenwich, about 5 miles (8 km.) north-northeast of Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).

Botsfordia cælata.

Acrotreta sagittalis taconica.

Billingsella salemensis.

Archæocyathus dwighti Walcott.

Hyalithellus micans (Billings).

Hyalithes americanus Billings.

Hyalithes communis Billings.

Hyalithes impar Ford.

Stenothecha elongata Walcott.

Stenothecha rugosa (Hall).

Microdiscus lobatus (Hall).

Microdiscus speciosus Ford.

Elliptocephala asaphoides Emmons.

Zacanthoides eatoni Walcott.

Ptychoparia cf. adamsi (Billings).

Protypus clavatus Walcott.

Solenopleura tumida Walcott.

33b. Lower Cambrian: Limestone, 1.5 miles (2.4 km.) east-southeast of North Greenwich, about 5 miles (8 km.) north-northeast of Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).

Botsfordia cælata.

Hyalithellus micans (Billings).

Hyalithes communis Billings.

Microdiscus lobatus (Hall).

Microdiscus speciosus Ford.

Elliptocephala asaphoides Emmons.

33d (same horizon as 15d). (For stratigraphic position and association, see p. 154.) Upper Cambrian: Thin-bedded blue limestone at the base of the first high point southwest of the J. J. Thomas ranch, on the east side of the Fish Spring Range, Juab County, Utah (L. D. Burling, 1905).

Obolus mcconnelli pelias.

Obolus rotundatus.

Lingulella isse.

Schizambon typicalis.

Acrotreta marjumensis.

33f. (For stratigraphic position and association, see p. 157.) Middle Cambrian: Shales about 400 feet (122 m.) above the Cambrian quartzitic sandstones on the western slope of the high peak southwest of Lookout Pass, Onaqui Range, west of Vernon, Tooele County, Utah (L. D. Burling, 1905).

**Obolus* (*Westonia*) *ella onaquiensis*.

Obolus (*Westonia*) *cf. ella onaquiensis*.

33i. (For stratigraphic position and association, see p. 158.) Lower Cambrian: About 100 feet (30.5 m.) above the Prospect Mountain quartzite, in the shale of the Pioche formation [Walcott, 1908f, p. 171], 0.25 mile (0.4 km.) below the Maxfield mine, Big Cottonwood Canyon, west front of the Wasatch Mountains southeast of Salt Lake City, Salt Lake County, Utah (L. D. Burling, 1905).

Obolus (*Westonia*) *ella*.

33j. (For stratigraphic position and association, see p. 149.) Middle Cambrian: Shale about 2,300 feet (701 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in Wasatch Canyon, east of Lakeview ranch, 5 miles (8 km.) north of Brigham, Boxelder County, Utah (L. D. Burling, 1905).

Obolus (*Westonia*) *wasatchensis*.

33l. (For stratigraphic position and association, see p. 153.) Upper Cambrian: Limestones in pass between the Pavant Mountains and the Canyon Range, a few hundred yards east of the divide, on the road between Holden and Scipio, Millard County, Utah (L. D. Burling, 1905).

Eoorthis desmopleura.

Solenopleura.

Illænurus.

- 33n. (For stratigraphic position and association, see p. 154.) Middle? Cambrian: Limestone pebbles, west front of the Pavant Mountains, collected in the wash at the mouth of Crow Creek, about 4 miles (6.4 km.) east of Fillmore, Millard County, Utah (L. D. Burling, 1905).
Acrotreta idahoensis alta.
- 33r. (For stratigraphic position and association, see p. 157.) Middle Cambrian: Limestones faulted against the Cambrian quartzites in a canyon about 1 mile (1.6 km.) east of Cricket Spring, Cricket Range (locally known as the Beaver River Range or the Beaver Mountains), northwest of Black Rock, Millard County, Utah (L. D. Burling, 1905).
 **Otusia utahensis*.
- 33t. (For stratigraphic position and association, see p. 150.) Middle Cambrian: Shale about 1,500 feet (457.2 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County, Utah (F. B. Weeks, 1905).
Obolus (*Westonia*) *wasatchensis*.
34. Lower Cambrian: Limestone on roadside a little west of the bridge over Poultney River at Low Hampton, about 5 miles (8 km.) east-northeast of Whitehall, Whitehall quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).

Botsfordia cælata.
Microdiscus lobatus (Hall).
Microdiscus speciosus Ford.
- 34g. (For stratigraphic position and association, see p. 153.) Passage beds between the Cambrian and Ordovician: Limestones about 1,000 feet (305 m.) above the valley on the east side of the Fish Spring Range, just west of the high point southwest of the J. J. Thomas ranch, Juab County, Utah (L. D. Burling, 1905).
Eoorthis desmopleura.
- 34i. (For stratigraphic position and association, see p. 154.) Upper Cambrian: Shales about 1 mile (1.6 km.) northeast of Sand Pass, at the south end of the Fish Spring Range, Juab County, Utah (C. D. Walcott and L. D. Burling, 1905).
Obolus rotundatus.
Lingulella desiderata.
Lingulella isse.
- 34m. (For stratigraphic position and association, see p. 151.) Middle Cambrian: Limestone about 765 feet (233.2 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County, Utah (L. D. Burling, 1905).
Micromitra (*Paterina*) *labradorica utahensis*.
Syntrophia cambria.
- 34n. (For stratigraphic position and association, see p. 158.) Middle Cambrian: Shales about 100 feet (30.5 m.) above the Tintic quartzite [G. O. Smith, 1900, p. 1], near the summit of the ridge between Mammoth and Eureka, Tintic special quadrangle (U. S. G. S.), Juab County, Utah (F. B. Weeks, 1905).
Obolus mcconnelli.
Obolus rotundatus.
- 34q. (For stratigraphic position and association, see p. 149.) Upper Cambrian: Shales about 3,800 feet (1,158.2 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in Wasatch Canyon, east of Lakeview Ranch, about 5 miles (8 km.) north of Brigham, Boxelder County, Utah (L. D. Burling, 1905).
Obolus mcconnelli pelias.
Acrotreta idahoensis alta.
- 34r. (For stratigraphic position and association, see p. 154.) Upper Cambrian: Limestones 1.5 miles (2.4 km.) northwest of Wahwah Spring, about halfway up the section to the north of the road at Cane Pass, Wahwah Mountains, Beaver County, Utah (F. B. Weeks, 1905).
Obolus rotundatus.
Lingulella isse.

- 34s. (For stratigraphic position and association, see p. 156.) Middle Cambrian: About 1,700 feet (518 m.) above the Tintic quartzite, in the Mammoth limestone of G. O. Smith [1900, p. 1, and historical geology sheet], in the saddle above and a little east of the Centennial Eureka mine, near the summit of the ridge between Mammoth and Eureka, Tintic special quadrangle (U. S. G. S.), Juab County, Utah (F. B. Weeks, 1905).

Obolus mcconnelli.

- 34t. (For stratigraphic position and association, see p. 154.) Upper Cambrian: Limestone 1.5 miles (2.4 km.) northwest of Wahwah Springs, about 80 feet (24.4 m.) below the highest point on the north side of the road at Cane Pass, Wahwah Mountains, Beaver County, Utah (F. B. Weeks, 1905).

Lingulella desiderata.

Lingulella isse.

- 34u. (For stratigraphic position and association, see p. 157.) Middle Cambrian: Shales about 950 feet (289.6 m.) above the Cambrian quartzitic sandstones 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah (L. D. Burling, 1905).

Obolus (Westonia) wasatchensis.

- 34v. (For stratigraphic position and association, see p. 155.) Middle? Cambrian: Limestone about 1,750 feet (533 m.) above the Cambrian quartzitic sandstones about 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah (L. D. Burling, 1905).

Obolus mcconnelli pelias.

35. Lower Cambrian: Limestones 1.5 miles (2.4 km.) north of Bald Mountain and 3.5 miles (5.6 km.) north-northwest of Greenwich, Schuylerville quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).

Obolus prindlei.

Lingulella granvillensis.

Obolella crassa.

Botsfordia cælata.

Acrotreta sagittalis taconica.

Stenotheca rugosa (Hall).

Platyceras primævum Billings.

Hyolithellus micans (Billings).

Hyolithellus micans rugosa Walcott.

Hyolithes communis Billings.

Elliptocephala asaphoides Emmons.

Solenopleura tumida Walcott.

- 35a. Lower Cambrian: Shaly limestone on the west slope of the summit of Bald Mountain, 3 miles (4.8 km.) north-northwest of Greenwich, Schuylerville quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).

Botsfordia cælata.

**Acrotreta emmonsii*.

Olenellus sp.

- 35c. (For stratigraphic position and association, see p. 130.) Lower Cambrian: Drift blocks of siliceous shale supposed to have come from the Mount Whyte formation [Walcott, 1908f, p. 214], found on the south slope of Mount Bosworth, about 500 feet (152 m.) northwest of the Canadian Pacific Railway track between Stephen and Hector, eastern British Columbia, Canada (Mr. and Mrs. C. D. Walcott and Mr. and Mrs. L. D. Burling, 1907).

**Micromitra (Paterina) wapta*.

**Obolus parvus*.

Acrothele colleni.

Wimanella simplex.

Hyolithellus.

Hyolithes.

**Albertella bosworthi* Walcott.

**Albertella helena* Walcott.

Bathyriscus.

Agraulos.

Ptychoparia.

Bathyriscus.

- 35d. (For stratigraphic position and association, see p. 130.) Lower Cambrian: About 3,150 feet (960.1 m.) below the Middle Cambrian, in the siliceous Lake Louise shale [Walcott, 1908f, p. 216], in cliff on the north side of Lake Louise, at its upper end, southeast of Laggan, on the Canadian Pacific Railway, Alberta, Canada (Mr. and Mrs. C. D. Walcott and Mr. and Mrs. L. D. Burling, 1907).

**Micromitra (Iphidella) louise*.

Cruziana.

Annelid trails.

- 35e. (For stratigraphic position and association, see p. 130.) Lower Cambrian: About 270 feet (82.3 m.) below the Middle Cambrian, in a greenish siliceous shale correlated with No. 3 of the Mount Whyte formation on Mount Bosworth [Walcott, 1908f, p. 214], in the amphitheater between Popes Peak and Mount Whyte, about 3 miles (4.8 km.) northwest of Lake Louise, southwest of Laggan on the Canadian Pacific Railway, Alberta, Canada (C. D. Walcott and L. D. Burling, 1907).

Micromitra (Paterina) wapta.

Obolus parvus.

Acrothele colleni.

Hyolithes billingsi Walcott.

Olenopsis.

Ptychoparia sp.

Albertella sp.

Bathyriscus.

Olenellus gilberti (Meek).

- 35f.** (For stratigraphic position and association, see p. 130.) Lower Cambrian: About 300 feet (91 m.) below the Middle Cambrian, in the limestone forming 6 of the Mount Whyte formation [Walcott, 1908c, p. 242 (11)], just above the tunnel on the north shoulder of Mount Stephen, about 3 miles (4.8 km.) east of Field, British Columbia, Canada (C. D. Walcott and L. D. Burling, 1907).
- | | |
|-------------------------------------|-------------------------------|
| Micromitra (Iphidella) pannula var. | Scenella varians Walcott. |
| Kutorgina cingulata. | Ptychoparia 3 sp. |
| Kutorgina? | Agraulos sp. |
| Acrotreta sagittalis taconica. | Protypus sp. |
| Nisusia festinata. | Olenellus canadensis Walcott. |
| Hyalolithes billingsi Walcott. | Olenellus gilberti (Meek). |
- 35g.** (For stratigraphic position and association, see p. 126.) Middle Cambrian: About 4,100 feet (1,250 m.) above the Lower Cambrian and 860 feet (262 m.) below the Upper Cambrian, in the shaly limestones in 2 of the Eldon limestone [Walcott, 1908f, p. 209], at the north end of the amphitheater northwest of the main ridge of Mount Bosworth, north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide between British Columbia and Alberta, Canada (C. D. Walcott and L. D. Burling, 1907).
- | | |
|------------------------|--------------------------------|
| Obolus mcconnelli var. | Isoxys cf. argentea (Walcott). |
| *Obolus membranaceus. | Ptychoparia 3 sp. |
- 35h.** (For stratigraphic position and association, see p. 130.) Lower Cambrian: About 375 feet (114 m.) below the Middle Cambrian, in the shales of No. 4 of the Mount Whyte formation [Walcott, 1908f, p. 214], on Mount Bosworth, north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide between British Columbia and Alberta, Canada (Mr. and Mrs. C. D. Walcott, Mr. and Mrs. L. D. Burling, and Helen and Stuart Walcott).
- | | |

| Acrotreta emmonsii. | Elliptocephala asaphoides Emmons. |
| *Acrotreta sagittalis taconica | Ptychoparia cf. adamsi (Billings). |
| Nisusia festinata. | Ptychoparia fitchi Walcott. |
| Protospongia sp. | Ptychoparia sp. |
| Platyceras primævum Billings | Prototypus clavatus Walcott. |
| Hyalithellus micans (Billings). | Zacanthoides eatoni Walcott. |
| Hyalithellus micans rugosa Walcott. | Olenoides fordi Walcott. |

- 38c. Lower Cambrian: Shale at the slate quarries on the west side of the valley 1 mile (1.6 km.) north of Middle Granville, Mettawee quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).

Botsfordia cælata.

39. Lower Cambrian: Limestone south of the Delaware and Hudson Railroad track, on the road running south-southwest from Low Hampton, about 5 miles (8 km.) east-northeast of Whitehall, Whitehall quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).

| | |
|--------------------------------|------------------------------|
| Botsfordia cælata. | Microdiscus speciosus Ford. |
| Acrotreta sagittalis taconica. | Prototypus clavatus Walcott. |
| Archæocyathus dwighti Walcott. | |

- 39a. Lower Cambrian: Limestone 0.25 mile (0.4 km.) north of Easton Station, 3 miles (4.8 km.) south of Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1887).

Botsfordia cælata.

Hyalithellus micans rugosa Walcott.
Microdiscus lobatus (Hall).

- 41 (same horizon as 51). (For stratigraphic position and association, see p. 141.) Lower Cambrian: Sandstone [see Walcott, 1891b, p. 260, for position in section] on Manuels Brook, Conception Bay, Newfoundland (C. D. Walcott, 1888).

| | |
|----------------------------------------------|-------------------------------------------------|
| *Obolella atlantica. | Coleoloides typicalis Walcott. |
| Hyalithellus micans (Billings). | Microdiscus bellimarginatus Shaler and Foerste. |
| Helenia bella Walcott. | Microdiscus helena Walcott. |
| Hyalithes princeps Billings. | Callavia bröggeri (Walcott). |
| Hyalithes quadricostatus Shaler and Foerste. | Ptychoparia attleborensis Shaler and Foerste. |
| Hyalithes similis Walcott. | Ptychoparia sp. |
| Hyalithes sp. | Solenopleura bombifrons Matthew. |
| Stenotheca rugosa (Hall). | Solenopleura howleyi Walcott. |
| Stenotheca rugosa acuticosta Walcott. | Avalonia manuelensis Walcott. |
| Stenotheca rugosa erecta Walcott. | Agraulos strenuus Billings. |
| Stenotheca rugosa lævis Walcott. | Agraulos strenuus nasutus Walcott. |
| Stenotheca rugosa pauper Billings. | Agraulos sp. |

Walcott [1891b, p. 260] cites the following additional species:

| | |
|---------------------------------|-------------------------------|
| Hyalithes impar Ford. | Platyceras primævum Billings. |
| Hyalithes terranovicus Walcott. | Microdiscus speciosus Ford. |
| Scenella reticulata Billings. | |

- 41a. (For stratigraphic position and association, see p. 141.) Lower Cambrian: Limestone [see Walcott, 1891b, p. 260] on the mainland beneath Topsail Head, Conception Bay, Newfoundland.

| | |
|-------------------------------------|-------------------------------------------------|
| Micromitra (Paterina) labradorica. | Hyalithes princeps Billings. |
| Obolella atlantica. | Microdiscus bellimarginatus Shaler and Foerste. |
| Scenella reticulata Billings. | Ptychoparia attleborensis Shaler and Foerste. |
| Hyalithellus micans (Billings). | Avalonia manuelensis Walcott. |
| Hyalithellus micans rugosa Walcott. | Agraulos strenuus Billings. |
| Hyalithes impar var. | |

Walcott [1891b, p. 260] cites the following additional species:

| | |
|------------------------------|----------------------------------|
| Microdiscus speciosus Ford. | Solenopleura bombifrons Matthew. |
| Microdiscus sp. undt. | Agraulos sp. |
| Callavia bröggeri (Walcott). | |

43. Ordovician: Shales on the summit of Moses Hill, 2 miles (3.2 km.) west of North Greenwich, near the line between the Schuylerville and Cambridge quadrangles (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1887).

Acrothele pretiosa.

- 43a. Lower Cambrian: Limestone 1 mile (1.6 km.) east-northeast of Salem, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott and W. P. Rust, 1887).

Botsfordia cælata.

Acrotreta sagittalis taconica.

Protospongia sp.

Hyalolithes impar Ford.

Microdiscus connexus Walcott.

Microdiscus lobatus (Hall).

Microdiscus speciosus Ford.

Agnostus desideratus Walcott.

Ptychoparia cf. *adamsi* (Billings).

Prototypus clavatus Walcott.

Zacanthoides eatoni Walcott.

- 44a (a little north of 44b). Lower Cambrian: Limestone on Valatie Kill, near the line between Nassau and Scho-dack townships, near line between Troy and Kinderhook quadrangles (U. S. G. S.), Rensselaer County, N. Y. (C. D. Walcott, 1887).

Acrotreta sagittalis taconica.

Microdiscus connexus Walcott.

- 44b (a little south of 44a). Lower Cambrian: Limestone near North Chatham, in the northern part of the Kinderhook quadrangle (U. S. G. S.), Columbia County, N. Y. (C. D. Walcott, 1887).

Micromitra (*Iphidella*) *pannula*.

Lingulella granvillensis.

Acrotreta sagittalis taconica.

Hyalithellus micans (Billings).

Agnostus sp.

- 45a. Lower Cambrian: Limestone at McNaughton Corner, 1 mile (1.6 km.) east of Salem, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y. (Ira Sayles, 1887).

Acrotreta sagittalis taconica.

Archæocyathus dwighti Walcott.

Archæocyathus rarus (Ford).

Hyalithellus micans (Billings).

Microdiscus lobatus (Hall).

Microdiscus speciosus Ford.

Solenopleura tumida Walcott.

Zacanthoides eatoni Walcott.

- 45b. Lower Cambrian: Limestone near the roadside about 1,200 feet (366 m.) east of Bristol's house, near Low Hampton, about 5 miles (8 km.) east-northeast of Whitehall, Whitehall quadrangle (U. S. G. S.), Washington County, N. Y. (Ira Sayles, 1887).

Obolus prindlei.

Acrotreta sagittalis taconica.

Platyceras primævum Billings.

Hyalithellus micans (Billings).

Hyalolithes americanus Billings.

Hyalolithes impar Ford.

Microdiscus speciosus Ford.

Elliptocephala asaphoides Emmons.

Solenopleura tumida Walcott.

- 47a. Lower Cambrian: Sandstone on the southwest side of Sallings Mountain, 2 miles (3.2 km.) east of Natural Bridge, Rockbridge County, Va. (C. D. Walcott, 1891).

**Kutorgina* sp. undt.

Obolella minor.

Hyalolithes communis Billings.

Olenellus sp.

- 47c. Lower Cambrian: Sandstone 2 miles (3.2 km.) west of bridge at Harpers Ferry, Jefferson County, W. Va. (C. D. Walcott, 1892).

Obolella minor.

Olenellus thompsoni (Hall).

- 47d (see 16f). Lower Cambrian: Sandstones 1 mile (1.6 km.) east-southeast of Smithsburg, Washington County, Md. (C. D. Walcott, 1892).

Obolella minor?

Olenellus thompsoni (Hall).

- 47e (see 16f). Lower Cambrian: Sandstone on Observatory Hill, 2 miles (3.2 km.) south of Keedysville, Washington County, Md. (C. D. Walcott, 1892).

Obolella minor.

Olenellus thompsoni (Hall).

- 47f (see 16f). Lower Cambrian: Sandstone at Eakles Mills, 2 miles (3.2 km.) south of Keedysville, Washington County, Md. (C. D. Walcott, 1892).

Obolella minor.

Olenellus thompsoni (Hall).

- 47h.** Middle Cambrian: Shales on Wolf Creek, 6 miles (9.6 km.) below Rocky Gap, Bland County, Va. (M. R. Campbell, 1893).
Dicellomus appalachia.
- 48d.** Middle Cambrian: Argillaceous shales in railroad cut alongside of gas house, city of York, York County, Pa. (H. E. Dickhaut, 1901).
 **Lingulella* sp. undt. b.
 **Acrothele yorkensis*.
- 49.** Lower Cambrian: Sandstone on Codorus Creek 0.125 mile (0.2 km.) below Meyer's mill, near Emigsville, York County, Pa. (Charles Schuchert, 1893).
Rustella edsoni?
Micromitra (Paterina) bella.
 **Yorkia wanneri*.
 | *Nisusia festinata*.
 | *Olenellus thompsoni crassimarginatus* Walcott.
- 49a.** Lower Cambrian: Sandstone on the Liverpool road, south of the schoolhouse, 3 miles (4.8 km.) northwest of York, York County, Pa. (Charles Schuchert, 1893).
Rustella edsoni.
Yorkia wanneri.
 | *Nisusia festinata*.
 | *Olenellus thompsoni crassimarginatus* Walcott.
- 49b.** Lower Cambrian: Sandstone in the continuation of the ridge mentioned in Locality 49c, 2 miles (3.2 km.) northwest of Emigsville, York County, Pa. (C. D. Walcott, 1892).
Obolella minor.
Olenellus thompsoni (Hall).
- 49c.** Lower Cambrian: Sandstone in ridge just north of the railway station at Emigsville, York County, Pa. (C. D. Walcott, 1892).
Obolella minor.
Olenellus thompsoni (Hall).
- 49d.** Lower Cambrian: Sandstone 3 miles (4.8 km.) east of Waynesboro, Franklin County, Pa. (C. D. Walcott, 1892).
Obolella minor.
Olenellus thompsoni (Hall).
- 49e.** Lower Cambrian: Sandstone 1 mile (1.6 km.) south of Mount Zion Church and 4 miles (6.4 km.) northeast of York, York County, Pa. (C. D. Walcott, 1892).
Obolella minor.
Olenellus thompsoni (Hall).
- 49f.** Lower Cambrian: Sandstones of Mount Holly Gap, South Mountain, Cumberland County, Pa. (C. D. Walcott, 1892).
Obolella minor?
Hyalithes sp.
Olenellus? sp.
- 49w.** Lower Cambrian: Limestone in railroad cut 0.25 mile (0.4 km.) south of Emigsville, York County, Pa. (C. D. Walcott, 1892).
Micromitra (Paterina) bella.
Nisusia festinata.
- 50.** Lower Cambrian: Shaly limestones 1.125 miles (1.8 km.) north of Stoner, 10 miles (16.1 km.) east-northeast of York, York County, Pa. (C. D. Walcott, 1892).
 **Acrothele decipiens*.
Olenellus.
- 50a.** Lower Cambrian: Sandstone 2 miles (3.2 km.) northwest of York, York County, Pa. (C. D. Walcott, 1892).
Obolella crassa?
Olenellus sp.
- 52.** (For stratigraphic position and association, see p. 140.) Lower Cambrian: Arenaceous shales just above the Prospect Mountain quartzite, in a stratigraphic position similar to that of the Pioche formation [Walcott, 1908f, p. 184], at the top of Prospect Mountain, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (J. P. Iddings and C. D. Walcott, 1880).
 **Micromitra (Paterina) prospectensis*.
Girvanella sp.
Scenella? conula Walcott.
Callavia nevadensis Walcott.
 | *Olenellus fremonti* Walcott.
 | *Peachella iddingsi* (Walcott).
 | *Dorypyge?* quadriceps (Hall and Whitfield).

- 53 (below 178a). (For stratigraphic position and association, see p. 138.) Lower Cambrian: Sandstones in the lower portion of 3d of the Waucoba Springs section [Walcott, 1908f, pp. 187 and 188], 1 mile (1.6 km.) east of Saline Valley road, about 2.5 miles (4 km.) east-northeast of Waucoba Springs, Inyo County, Cal. (C. D. Walcott, 1897).
- | | |
|--------------------------|----------------------------|
| Mickwitzia occidentis. | Ethmophyllum gracile Meek. |
| Obolella vermilionensis. | Hyalolithes sp. |
| *Trematobolus excelsis. | Wanneria gracile Walcott. |
| Archaeocyathus. | |
- 53a. (For stratigraphic position and association, see p. 138.)
Obolella sp.
54. (For stratigraphic position and association, see p. 140.) Middle Cambrian: Eldorado limestone [Walcott, 1908f, p. 184] on east slope of Prospect Mountain, in New York Canyon, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1886).
- Lingulella arguta.
Lingulella punctata.
- 54a (=31e). (For stratigraphic position and association, see p. 151.) (C. D. Walcott and L. D. Burling, 1906.)
- | | |
|----------------------------------------------|--------------------------------|
| Micromitra (Paterina) labradorica utahensis. | Isoxys cf. argentea (Walcott). |
| Obolus (Westonia) ella. | Ptychoparia. |
| Acrothele turneri? | |
- 54b. (For stratigraphic position and association, see p. 148.) Upper Cambrian: About 1,200 feet (365.8 m.) above the Middle Cambrian and 25 feet (7.6 m.) below the top of the Upper Cambrian, in the upper part of the limestone forming 1 of the St. Charles limestone [Walcott, 1908f, p. 191], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah (C. D. Walcott and L. D. Burling, 1906).
- | | |
|-----------------------|---------------------|
| Lingulella manticula. | Syntrophia nundina. |
| Eoorthis desmopleura. | Dikellocephalus. |
- 54c. (For stratigraphic position and association, see p. 148.) Upper Cambrian: About 1,100 feet (335.3 m.) above the Middle Cambrian and 120 feet (36.6 m.) below the top of the Upper Cambrian, in the central part of the limestone forming 1 of the St. Charles limestone [Walcott, 1908f, p. 192], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah (C. D. Walcott and L. D. Burling, 1906).
- | | |
|-----------------------|---------------|
| Schizambon typicalis. | Solenopleura. |
| Eoorthis desmopleura. | Menocephalus. |
| *Eoorthis newberryi. | Illænurus. |
| Syntrophia nundina. | |
- 54d. (For stratigraphic position and association, see p. 148.) Upper Cambrian: About 1,050 feet (320 m.) above the Middle Cambrian and 175 feet (53.3 m.) below the top of the Upper Cambrian, in the lower part of the limestone forming 1 of the St. Charles limestone [Walcott, 1908f, p. 192], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah (C. D. Walcott and L. D. Burling, 1906).
- | | |
|------------------------------------|---------------|
| Lingulella (Lingulepis) acuminata. | Menocephalus. |
| Eoorthis desmopleura. | Solenopleura. |
| Eoorthis newberryi. | Asaphus?. |
| Agnostus. | |
- 54e. (For stratigraphic position and association, see p. 149.) Upper Cambrian: About 200 feet (61 m.) above the Middle Cambrian and 1,025 feet (212.4 m.) below the top of the Upper Cambrian, in limestones forming 3 of the St. Charles limestone [Walcott, 1908f, p. 193], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah (Mrs. C. D. Walcott, Stuart Walcott, and L. D. Burling, 1906).

Acrothele subsidua. | *Microdiscus*.
Acrotreta cf. *idahoensis*. | *Zacanthoides idahoensis* Walcott.
Ptychoparia 3 sp. | *Menocephalus*.

59m. (For stratigraphic position and association, see p. 147.) Lower Cambrian: Weisner quartzite in the Roan iron mine, Bartow County, Ga. (S. W. McCallie, 1900).

Obolella cf. atlantica. | Stenotheca cf. rugosa (Hall).
 Obolella cf. crassa. | Olenellus thompsoni (Hall).
 Archæocyathus?.

60. (For stratigraphic position and association, see p. 139.) Middle Cambrian: Limestones in upper beds of Secret Canyon shale, across the canyon from the dump of the old Richmond mine shaft, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

Lingulella clarkei. | Agnostus prolongus Hall and Whitfield.
 Lingulella desiderata. | Ptychoparia maculosa (Hall and Whitfield).
 Lingulella sp. | Ptychoparia nnisulcata (Hall and Whitfield).
 Acrotreta pyxidicula.

60b. (For stratigraphic position and association, see p. 130.) Lower Cambrian: About 2,300 feet (702 m.) below the Mount Whyte formation and 200 to 300 feet (61 to 92 m.) above the Lake Louise shale, in the St. Piran sandstone [Walcott, 1908a, p. 4], at Vermilion Pass, on the Continental Divide between British Columbia and Alberta, west-southwest of Castle on the Canadian Pacific Railway, Alberta, Canada (C. D. Walcott, 1909).

* Obolella vermilionensis.
 Wanneria gracile Walcott.

61. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone in the Dunderberg shale [Walcott, 1908f, p. 184], a little south of the Hamburg mine, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott and C. H. H., 1882).

Micromitra sculptilis. | Acrotreta idahoensis alta.
 Obolus anceps. | *Acrotreta spinosa.
 Obolus mæra. | Acrotreta sp.
 Obolus nundina. | Agnostus prolongus Hall and Whitfield.
 Lingulella desiderata. | Agnostus tumidosus Hall and Whitfield.
 Lingulella manticula. | Ptychoparia granulosa (Hall and Whitfield).
 Lingulella punctata. | Ptychoparia maculosa (Hall and Whitfield).
 Acrotreta attenuata. | Ptychoparia unisulcata (Hall and Whitfield).
 Acrotreta idahoensis.

62. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone in the Dunderberg shale [Walcott, 1908f, p. 184], in canyon immediately north of Adams Hill, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

Micromitra sculptilis. | Acrotreta spinosa.
 Obolus discoideus. | Agnostus prolongus Hall and Whitfield.
 Lingulella manticula. | Ptychoparia breviceps (Walcott).
 Lingulella punctata. | Arethnsina americana Walcott.

62a. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone on east side of Sierra Canyon, opposite the Jackson mine, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

Acrotreta spinosa.
 Ptychoparia granulosa (Hall and Whitfield).
 Ptychoparia simulator (Hall and Whitfield).

63. (For stratigraphic position and association, see p. 139.) Lower Ordovician: At the base of the Pogonip limestone northeast of Adams Hill, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

*Obolus anceps. | Schizambon?.
 *Elkania ambigua. | Syntrophia nundina.
 Acrotreta idahoensis alta.

64. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone near the Bullwhacker mine, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

Obolus discoideus.
 Obolus (Westonia) iphis.
 Agnostus prolongus Hall and Whitfield.

65. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone on the east side of Sierra Canyon, opposite Pinnacle Peak, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (Arnold Hague and J. P. Iddings, 1880).

Acrotreta idahoensis alta.
 Acrotreta spinosa.

66. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Dunderberg shale [Walcott, 1908f, p. 134], on the first ridge north of the Dunderberg mine, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).
Obolus discoideus.
Agnostus prolongus Hall and Whitfield.
Arethusina americana Walcott.

Syntrophia barabuensis.
Illænurus quadratus Hall.
Spirodentalium osceola Walcott.
Bellerophon antiquatus Whitfield.
- 78a. Upper Cambrian: "St. Croix sandstone" in the topmost quarry on Mount Washington, near Eau Claire, Eau Claire County, Wis. (L. C. Wooster, 1883).
Obolus sp. undt.
Dicellomus pectenoides.
Dicellomus politus.
 **Agraulos?* *thea* Walcott.
Crepicephalus iowensis (Hall).
- 78b. Upper Cambrian: "St. Croix sandstone" 50 feet (15.2 m.) above St. Croix River, near the landing at Osceola, Polk County, Wis. (Cooper Curtice, 1884).
Lingulella mosia.
Lingulella similis.
Finkelburgia osceola.
- 78c. Upper Cambrian: "St. Croix sandstone" at Osceola, Polk County, Wis. (C. Schuchert, 1893).
Obolus (*Westonia*) *aurora*.
Lingulella oweni.
Lingulella winona.
Lingulella winona convexa.
- 78d. Upper Cambrian: The upper portion of the "St. Croix sandstone" exposed in the bluffs at La Crosse, La Crosse County, Wis. (C. D. Walcott, 1898).
Obolus matinalis.
- 78s (=78). (C. Schuchert, 1893.)
Obolus (*Westonia*) *aurora*.
Lingulella mosia.
Lingulella mosia osceola.
Lingulella winona convexa.
Finkelburgia finkelburgi.
Finkelburgia osceola.
Finkelburgia osceola corrugata.

- 79.** Upper Cambrian: "St. Croix sandstone" in bluff near Hudson, St. Croix County, Wis. (L. C. Wooster, 1883).
Obolus matinalis.
 **Obolus mickwitzi*.
Obolus (Westonia) aurora.
Lingulella mosia.
Lingulella winona.
Lingulella winona convexa.
Lingulella (Lingulepis) acuminata.
Billingsella coloradoensis.
Ptychoparia wisconsinensis (Owen).
- 79'** (=79, though from a slightly different horizon). (Chas. Schuchert, 1893.)
Obolus matinalis.
Obolus mickwitzi.
- 79a.** Upper Cambrian: "St. Croix sandstone," quarry and ledge 0.5 mile (0.8 km.) southeast of the county courthouse, Menomonie, Dunn County, Wis. (L. C. Wooster, 1883).
Lingulella winona convexa.
 **Protorthis laevis*.
Billingsella coloradoensis.
Eoorthis sp.
Finkelburgia osceola.
- 79b.** Upper Cambrian: "St. Croix sandstone" in shaly beds 4 feet (1.2 m.) above the water, near Hudson, St. Croix County, Wis. (J. F. James, 1889).
Obolus matinalis.
Obolus mickwitzi.
Lingulella (Lingulepis) acuminata.
Finkelburgia osceola.
- 79s.** Upper Cambrian: "St. Croix sandstone" in bluff near Hudson, St. Croix County, Wis. (C. Schuchert, 1893).
Lingulella mosia.
Dicellomus politus.
- 79z.** Middle Cambrian: "St. Croix sandstone" near the flour mill on Beaver Creek, north of Galesville, Trempealeau County, Wis. (Cooper Curtice, 1882; L. C. Wooster, 1883). (See p. 159.)
Lingulella (Lingulepis) acuminata.
Dicellomus politus.
- 80.** Upper Cambrian: "St. Croix sandstone" 0.66 mile (1.1 km.) southwest of the railway depot, Menomonie, Dunn County, Wis. (L. C. Wooster, 1883).
Lingulella ampla.
Lingulella winona convexa.
Dicellomus politus.
Finkelburgia osceola.
- 80a.** Upper Cambrian: "St. Croix sandstone" 4 miles (6.4 km.) north of Reedsburg, Sauk County, Wis. (L. C. Wooster, 1883).
Lingulella similis.
Billingsella coloradoensis.
 **Eoorthis remnicha*.
Eoorthis remnicha sulcata.
Finkelburgia osceola.
- 81.** Upper Cambrian: "St. Croix sandstone" 1 mile (1.6 km.) east-northeast of Devils Lake, Sauk County, Wis. (L. C. Wooster, 1883).
Finkelburgia finkelburgi.
- 81b.** Upper Cambrian: "St. Croix sandstone" near Devils Lake, Sauk County, Wis. (Cooper Curtice, 1884).
Obolus (Westonia) stoneanus.
 **Eoorthis diablo*.
Finkelburgia finkelburgi.
Syntrophia barabuensis.
- 81o.** Upper Cambrian: "St. Croix sandstone" on the railroad track below the Cliff House, Devils Lake, Sauk County, Wis. (J. F. James, 1889).
Syntrophia barabuensis.
- 82** (see 82s). Upper Cambrian: "St. Croix sandstone" on the bank of St. Croix River, at St. Croix Falls, Polk County, Wis. (L. C. Wooster, 1883).
Lingulella (Lingulepis) acuminata.
- 82a.** Upper Cambrian: "St. Croix sandstone" 25 feet (7.6 m.) above the water level, near the Knapp, Stout and Company's buildings, Menomonie, Dunn County, Wis.
Obolus matinalis.
Lingulella phaon.
- 82b** (see 339d; may be same locality). Upper Cambrian: "St. Croix sandstone" along the railroad track near Taylors Falls, Chisago County, Minn. (W. A. Finkelburg).
 **Curticia elegantula*.
Obolus matinalis.
Dicellomus politus.

- 82c. Upper Cambrian: Conglomerate beds in the "St. Croix sandstone" in point below Franconia, Chisago County, Minn. (W. A. Finkelnburg).
Lingulella similis.
- 82s (see S2). Upper Cambrian: "St. Croix sandstone" on the bank of St. Croix River, St. Croix Falls, Polk County, Wis. (C. Schuchert, 1893).
Obolus matinalis.
Lingulella (Lingulepis) acuminata.
83. Upper Cambrian: "St. Croix sandstone" near Trempealeau, Trempealeau County, Wis. (Cooper Curtice and G. H. Squiers, 1884).
Obolus matinalis.
Dicellomus politus.
Eoorthis diablo.
 **Finkelnburgia finkelnburgi*.
Finkelnburgia osceola.
Syntrophia barabuensis.
Chariocephalus whitfieldi Hall.
- 83¹ (=135c). (Chas. Schuchert, 1893.)
Billingsella coloradoensis.
Finkelnburgia finkelnburgi.
Finkelnburgia osceola.
- 83³. Upper Cambrian: Green-sand horizon in the "St. Croix sandstone," below the "fifth trilobite bed" of Owen, at Trempealeau, Trempealeau County, Wis. (Chas. Schuchert, 1893).
Billingsella coloradoensis.
Chariocephalus whitfieldi Hall.
- 83⁴. Middle Cambrian: "St. Croix sandstone," in beds characterized by the presence of *Crepicephalus iowensis*, at Trempealeau, Trempealeau County, Wis. (C. Schuchert, 1893). (See p. 159.)
Obolus matinalis.
84. Middle Cambrian: "St. Croix sandstone" at Dresbach, opposite the mouth of Black River, Winona County, Minn. (Cooper Curtice, 1884). (See p. 159.)
Obolus namouna.
Obolus rhea.
Lingulella ampla.
Lingulella (Lingulepis) acuminata.
Dicellomus politus.
- 84a. Upper Cambrian: "St. Croix sandstone," River Junction, Houston County, 20 miles (32.2 km.) below Dresbach, Minn. (Cooper Curtice, 1884).
Lingulella phaon^a.
Billingsella coloradoensis.
Syntrophia primordialis.
Dikellocephalus misa Hall.
Chariocephalus whitfieldi Hall.
- 84f. Middle Cambrian: "St. Croix sandstone" at Dresbach, opposite the mouth of Black River, Winona County, Minn. (W. A. Finkelnburg, 1897). (See p. 159.)
Lingulella ampla.
Dicellomus politus.
- 84s. Middle Cambrian: "St. Croix sandstone" near Dakota, Winona County, Minn. (Chas. Schuchert, 1893). (See p. 159.)
Lingulella ampla.
Lingulella (Lingulepis) acuminata.
Dicellomus politus.
- 85 (=85s). Upper Cambrian: "St. Croix sandstone" at Prairie du Sac, Sauk County, Wis. (Cooper Curtice, 1884).
Obolus (Westonia) stoneanus.
 **Lingulella mosia*.
- 85a. Upper Cambrian: "St. Croix sandstone" at Brown's quarry, Prairie du Sac, Sauk County, Wis. (Cooper Curtice, 1884).
Lingulella oweni.
- 85s (=85, though possibly from a slightly different bed). Upper Cambrian: "St. Croix sandstone" at Prairie du Sac, Sauk County, Wis. (Chas. Schuchert, 1893).
Obolus (Westonia) aurora.
 **Obolus (Westonia) stoneanus*.
Lingulella mosia.
Lingulella oweni.
Lingulella winona.
Lingulella winona convexa.
Ilænurus quadratus Hall.
Dikellocephalus minnesotensis Owen.
Dikellocephalus pepinensis Owen.

^a May be from a horizon different from that of the other species.

85x. Upper Cambrian: Upper beds of the "St. Croix sandstone" near Mazomanie, Dane County, Wis. (Chas. Schuchert, 1893).

| | |

90c. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Conasauga limestone near Kimbrel, Bibb County, Ala. (Chas. Butts, 1904).

**Lingulella buttsi*.

^a Winchell [1886, p. 317] gives the type locality as St. Croix sandstone in sewer excavations at the corner of Brush and Main streets, Red Wing, Minn.

90x (=94a). (For stratigraphic position and association, see p. 147.) Middle Cambrian: In and attached to the outer surface of siliceous nodules in the Conasauga ("Coosa") shale, Coosa Valley, east of Center, Cherokee County, Ala. (A. M. Gibson, 1884, and Cooper Curtice, 1885).

Micromitra alabamaensis.

**Lingulella hayesi*.

**Acrothele bellula*.

**Acrotreta kutorgai*.

Ptychoparia.

Anomocare.

Olenoides curticei Walcott.

Laotira cambria Walcott.

Brooksella alternata Walcott.

91. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Conasauga ("Coosa") shale at Cedar Bluff, Cherokee County, Ala. (A. M. Gibson, 1884, and Cooper Curtice, 1885).

Obolus willisi.

Lingulella nanno.

**Lingulella quadrilateralis*.

Dicellomus appalachia.

92b (the specimens are labeled 1092b). Upper Cambrian: Limestone on Buffalo Creek, 2 miles (3.2 km.) southeast of Buffalo Mills, Rockbridge County, Va. (C. D. Walcott, 1898).

Obolus matinalis.

Lingulella (Lingulepis) acuminata.

92x. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Conasauga ("Coosa") shale at Yanceys Bend, Coosa River, southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Obolus sinoe.

Lingulella similis?

93. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales and limestones at the base of the Knox dolomite near Jordan's, just below the ford on Cowan Creek, about 8 miles (12.8 km.) southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Obolus willisi.

Lingulella desiderata.

93a. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales and limestones at the base of the Knox dolomite on Terrapin Creek road from Center to Amberson, Cherokee County, Ala. (Cooper Curtice, 1885).

Lingulella desiderata?

93n (16 of section). (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales in the southern part of Jordan's farm, near Jordan's crossroads, about 8 miles southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Obolus willisi.

93o (=93). (For stratigraphic position and association, see p. 147.) (Cooper Curtice, 1885.)

Lingulella desiderata.

93x. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales on the Clarke farm, near the ford across Cowan Creek, about 2 miles (3.2 km.) north of Jordan's crossroads, southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Obolus willisi.

94 (see 94a, 94o, 94x, and 94xx; 8½ of section). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales 0.25 mile (0.4 km.) beyond Steel Ford, Cowan Creek, about 8 miles (12.8 km.) southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

**Micromitra alabamaensis*.

Obolus willisi.

94a (=shales in which nodules of 90x are embedded; see 94, 94o, 94x, and 94xx; 9 of section). (For stratigraphic position and association, see p. 147.) (Cooper Curtice, 1885.)

Micromitra alabamaensis.

Obolus willisi.

Lingulella hayesi.

94o (see 94, 94a, 94x, and 94xx; 12 of section). (For stratigraphic position and association, see p. 147.) Upper Cambrian: Limestone at base of dolomite 0.25 mile (0.4 km.) beyond Givens Ford, Cowan Creek, about 8 miles (12.8 km.) southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Micromitra alabamaensis.

Lingulella desiderata.

Acrotreta sp.

94x (see 94, 94a, 94o, and 94xx). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales 0.06 mile (0.1 km.) south of Givens mill, Cowan Creek, about 8 miles (12.8 km.) southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Acrothele bellula.

94xx (see 94, 94a, 94o, and 94x; 10 of section). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone at base of dolomite at Givens mill, Cowan Creek, about 8 miles (12.8 km.) southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Lingulella desiderata.

Acrotreta sp.

95a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales on Spring Creek, near old tram crossing north of the Center road, Cowan Creek valley, southeast of Center, Cherokee County, Ala. (Cooper Curtice, 1885).

Micromitra alabamaensis.

96. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Limestone near the ford on the Cedartown road, 1.5 miles (2.4 km.) south of Rome, Floyd County, Ga. (Cooper Curtice, 1885).

Micromitra (Iphidella) pannula.

Lingulella desiderata.

Obolus rotundatus.

**Lingulella leos*.

96b. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales in a railroad cut on the Southern Railway, near Cave Spring, 10 miles (16.1 km.) southwest of Rome, Floyd County, Ga. (Cooper Curtice, 1885).

Obolus willisi.

96x. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone 1 mile (1.6 km.) north of Adairsville, 15 miles (24.2 km.) northwest of Cartersville, Cartersville quadrangle (U. S. G. S.), Bartow County, Ga. (Cooper Curtice, 1885).

**Acrotreta concentrica*.

97 (=97x and S97x, though possibly from a slightly different horizon). Upper Cambrian: "St. Croix sandstone" at Reads Landing, foot of Lake Pepin, Wabasha County, Minn. (Cooper Curtice, 1884).

Obolus (Westonia) aurora.

Billingsella coloradoensis.

Lingulella oweni.

Eoorthis sp.

Lingulella similis.

**Syntrophia primordialis argia*.

Dicellomus politus.

97a. Upper Cambrian: "St. Croix sandstone" near Winfield, Jefferson County, Wis. (Cooper Curtice, 1884).

Lingulella similis.

Eoorthis remnicha sulcata.

Lingulella (Lingulepis) acuminata.

**Eoorthis remnicha winfieldensis*.

Billingsella coloradoensis.

Eoorthis sp.

Eoorthis remnicha.

97b. Upper Cambrian: In the "St. Croix sandstone" below the green-sand bed and about 25 feet (7.6 m.) above St. Croix River, at Franconia, Chisago County, Minn. (Cooper Curtice, 1884).

Obolus matinalis.

Lingulella (Lingulepis) acuminata.

Billingsella coloradoensis.

97c. Upper Cambrian: "St. Croix sandstone" at Winfield, Jefferson County, Wis. (Cooper Curtice, 1884).

Lingulella similis.

97s. Upper Cambrian: "St. Croix sandstone" at Franconia, Chisago County, Minn. (Chas. Schuchert, 1893).

Lingulella similis.

97x (=97, though possibly from a slightly different horizon). (Chas. Schuchert, 1893.)

Eoorthis remnicha sulcata.

S97x (=97, though possibly from a slightly different horizon). (Chas. Schuchert, 1893.)

Dicellomus politus.

Billingsella coloradoensis.

98 (=98x, though from a slightly different horizon). Upper Cambrian: "St. Croix sandstone" near Eau Claire Eau Claire County, Wis. (Cooper Curtice, 1884).

Obolus matinalis.

Lingulella phaon.

**Obolus namouna*.

Lingulella (Lingulepis) acuminata.

**Obolus rhea*.

Dicellomus politus.

Lingulella ampla.

Ptychoparia onustus (Whitfield).

Lingulella mosia osceola.

Hyolithes.

98a. Upper Cambrian: "St. Croix sandstone" at Marine Mills, on St. Croix River, Washington County, Minn.
Lingulella mosia. | *Ptychoparia* sp.
Dicellomus politus. | *Ptychaspis granulosa* (Owen).
Billingsella coloradoensis.

98x (=98, though from a slightly different horizon). (Cooper Curtice, 1884.)
Obolus matinalis. | **Lingulella phaon*.
Lingulella mosia. | *Dicellomus politus*.

99. Upper Cambrian: "St. Croix sandstone" at Minneiska (Miniska), on Mississippi River, near the line between Wabasha and Winona counties, Minn. (Cooper Curtice, 1884).
Syntrophia primordialis.

99a. Upper Cambrian: "St. Croix sandstone" near Pilot Knob, Adams County, Wis. (Cooper Curtice, 1884).
Lingulella mosia.
Lingulella (*Lingulepis*) *acuminata*.
Eoorthis remnicha winfieldensis.

100. Upper Cambrian: "St. Croix sandstone" near Menomonie, Dunn County, Wis. (Cooper Curtice, 1884).
Obolus matinalis. | *Lingulella winona convexa*.
Obolus sp. undt. | *Dicellomus pectenoides*.
Lingulella ampla. | *Dicellomus politus*.
Lingulella mosia. | *Billingsella coloradoensis*.

100a. Upper Cambrian: "St. Croix sandstone" at Ettrick, Trempealeau County, Wis. (Cooper Curtice, 1884).
Dicellomus politus.

101 (25 feet above 101a; same horizon as 102). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Rogersville shale just above the road in the hill west of the schoolhouse 3.5 miles (5.6 km.) southwest of Rogersville, on the road to Melinda Ferry [see Keith, 1896a, areal geology sheet], Hawkins County, Tenn. (R. R. Gurley, 1887).
Micromitra (*Iphidella*) *pannula*.
Obolus lamborni minimus.

101a (25 feet below 101). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Rogersville shale just above the road in the hill west of the schoolhouse 3.5 miles (5.6 km.) southwest of Rogersville, on the road to Melinda Ferry [see Keith, 1896a, areal geology sheet], Hawkins County, Tenn. (R. R. Gurley, 1887).
 **Obolus lamborni minimus*.
Lingulella desiderata.
 **Acrotreta rudis*.

101b. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Rogersville shale just east of the schoolhouse 3.5 miles (5.6 km.) southwest of Rogersville, on the road to Melinda Ferry [see Keith, 1896a, areal geology sheet], Hawkins County, Tenn. (R. R. Gurley, 1887).
Obolus lamborni.
Obolus willisi.
Lingulella desiderata.

102 (same horizon as 101). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Rogersville shale just south of road 0.5 mile (0.8 km.) southwest of Rogersville, on the road to Melinda Ferry [see Keith, 1896a, areal geology sheet], Hawkins County, Tenn. (R. R. Gurley, 1887).
Obolus lamborni.
Dicellomus appalachia.

102c. (For stratigraphic position and association, see p. 147.) Middle Cambrian: First shale south of the Estillville pike, 3.5 miles (5.6 km.) east of Rogersville, Greeneville quadrangle (U. S. G. S.), Hawkins County, Tenn. (R. R. Gurley, 1887).
Acrotreta rudis.

103 (below 103a). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Second shale south of the ridge of sandstone in the Rome formation ("Town Knobs"), on the road from Rogersville to Dodson Ford, near the line between the Morristown and Greeneville quadrangles (U. S. G. S.), Hawkins County, Tenn. (R. R. Gurley, 1887).
Obolus lamborni.

- 103a (immediately underlying 103b). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Upper part of the second shale south of the ridge of sandstone in the Rome formation ("Town Knobs"), on the road from Rogersville to Dodson Ford, near the line between the Morristown and Greeneville quadrangles (U. S. G. S.), Hawkins County, Tenn. (R. R. Gurley, 1887).

Obolus lamborni minimus.

Dicellomus appalachia.

- 103b (immediately overlying 103a). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Third limestone (100 yards (90 m.) down the road toward the river from 103a) south of the ridge of sandstone in the Rome formation ("Town Knobs"), on the road from Rogersville to Dodson Ford, near the line between the Morristown and Greeneville quadrangles (U. S. G. S.), Hawkins County, Tenn. (R. R. Gurley, 1887).

Lingulella desiderata.

104. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shale in railroad cut 0.5 mile (0.8 km.) from Rogersville, on the road to Holston River, near the line between the Morristown and Greeneville quadrangles (U. S. G. S.), Hawkins County, Tenn. (R. R. Gurley, 1887).

Dicellomus appalachia.

105. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Limestone in Knox dolomite at Bishops mill, Hancock County, Tenn. (Ira Sayles, 1884).

Lingulella (Lingulepis) acuminata.

- 105t. (For stratigraphic position and association, see p. 153.) Lower Ordovician: Thiu-bedded bluish-gray limestone [Walcott, 1908f, p. 173, and Pls. XIII and XIV], at the summit of Notch Peak, House Range, Millard County, Utah (C. D. Walcott, F. B. Weeks, and L. D. Burling, 1905).

**Obolus (Westonia) notchensis*.

Eoorthis desmopleura.

Raphistoma sp.

- 105x. (For stratigraphic position and association, see p. 148.) Middle Ordovician: Gray siliceous shales just below a band of quartzitic sandstones probably corresponding in position to the upper part of the Simpson formation of the Oklahoma section, in Wasatch Canyon, east of Lakeview ranch, about 5 miles (8 km.) north of Brigham, Boxelder County, Utah (F. B. Weeks and L. D. Burling, 1905).

**Obolus (Westonia) elongatus*.

106. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales of the Rome formation on the roadside at the eastern base of Shooks Gap, in Bays Mountains, 10 miles (16.1 km.) southeast of Knoxville [see Keith, 1895, areal geology sheet], Knox County, Tenn. (Cooper Curtice, 1885).

Lingulella similis.

- 106a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Reddish-brown shales in middle of valley east of Shooks Ridge, in Bays Mountains, 10 miles (16.1 km.) southeast of Knoxville, Knox County, Tenn. (Cooper Curtice, 1885).

Obolus willisi.

- 107 (just above 107a). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone in Bull Run, northwest of Copper Ridge [Keith, 1896b, areal geology sheet], 11 miles (17.6 km.) northwest of Knoxville, Knox County, Tenn. (Cooper Curtice, 1885).

Dicellomus appalachia.

Wimanelia harlanensis.

- 107a (just below 107, above 107b). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales in railroad cut in Bull Run, northwest of Copper Ridge [Keith, 1896b, areal geology sheet], 11 miles (17.6 km.) northwest of Knoxville, Knox County, Tenn. (Cooper Curtice, 1885).

Obolus willisi.

Lingulella desiderata ?.

- 107b (below 107a). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales and sandstones of the Rome formation in railroad cut in Bull Run, northwest of Copper Ridge [Keith, 1896b, areal geology sheet], 11 miles (17.6 km.) northwest of Knoxville, Knox County, Tenn. (Cooper Curtice, 1885).

Obolus willisi.

Lingulella ?.

| *Dicellomus appalachia*.

| *Linnarssonella tennesseensis*.

- 107o (just above 107u). (For stratigraphic position and association, see p. 147.) Upper Cambrian: Limestones and shales at the base of the Knox dolomite west of the top of Copper Ridge, near the Southern Railway cut, about 10 miles (16.1 km.) northwest of Knoxville [see Keith, 1896b, areal geology sheet], Knox County, Tenn. (Cooper Curtice, 1885).
Lingulella desiderata.
Lingulella (Lingulepis) acuminata.
Acrotreta kutorgai.
- 107u (just below 107o). (For stratigraphic position and association, see p. 147.) Upper Cambrian: Limestones and shales at the base of the Knox dolomite west of the top of Copper Ridge, near the Southern Railway cut, about 10 miles (16.1 km.) northwest of Knoxville [see Keith, 1896b, areal geology sheet], Knox County, Tenn. (Cooper Curtice, 1885).
Lingulella desiderata?.
Acrotreta kutorgai.
108. Upper Cambrian: Sandstone 1 mile (1.6 km.) south of Poughkeepsie, Dutchess County, N. Y. (C. D. Walcott, 1886).
Lingulella (Lingulepis) acuminata.
- 109 (see 367k). Upper Cambrian: Sandstone 25 feet (7.6 m.) above the Archean 1.5 miles (2.4 km.) south of Deweys Bridge, on the Champlain Canal, Washington County, N. Y. (C. D. Walcott, 1886).
Lingulella (Lingulepis) acuminata.
- 110 (just below 110a). Upper Cambrian: Shaly calcareous sandstone resting on massive layers of Potsdam sandstone, east side of the town of Whitehall, Washington County, N. Y. (C. D. Walcott, 1886).
Lingulella (Lingulepis) acuminata.
- 110a (just above 110). Upper Cambrian: Sandstone on the east side of the town of Whitehall, Washington County, N. Y. (C. D. Walcott, 1886).
Lingulella (Lingulepis) acuminata.
111. Upper Cambrian: At the top of the Potsdam sandstone on Marble River, 1 mile (1.6 km.) south of Chateaugay, Franklin County, N. Y. (C. D. Walcott, 1886).
Lingulella (Lingulepis) acuminata.
113. Upper Cambrian: "St. Croix sandstone" at La Grange Mountain (or Barn Bluff), near Red Wing, Goodhue County, Minn. (Cooper Curtice, 1884).
Lingulella mosia.
Lingulella winona.
- 114 (above 114a). (For stratigraphic position and association, see p. 140.) Upper Cambrian: Upper sandstone beds on Little Belle Island, Conception Bay, Newfoundland (C. D. Walcott, 1888).
Lingulella bella.
Lingulella bellula.
- 114a (below 114). (For stratigraphic position and association, see p. 140.) Upper Cambrian: Sandy shales underlying beds of Locality 114, Little Belle Island, Conception Bay, Newfoundland (C. D. Walcott, 1888).
Lingulella bella.
 **Lingulella bellula*.
- 114b. (For stratigraphic position and association, see p. 140.) Lower Ordovician: Sandstone 1 mile (1.6 km.) north of Lance Cove, Great Belle Island, Conception Bay, Newfoundland (C. D. Walcott, 1888).
 **Obolus (Lingulobolus) affinis*. | *Obolus (Westonia) rogersi*.
 **Obolus (Lingulobolus) spissus*. | **Lingulella bella*.
116. Upper Cambrian: "St. Croix sandstone" in excavation on Wells farm, 2 miles (3.2 km.) west of Baraboo, Baraboo quadrangle (U. S. G. S.), Sauk County, Wis.
 **Billingsella major*.
117. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales on the road north from Greenville, Greene County, Tenn. (Cooper Curtice, 1886).
Lingulella desiderata.
- 117c. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shale at Buckingham Ford on Hollis Creek, 5 miles (8 km.) southeast of Greenville, Greene County, Tenn. (Cooper Curtice, 1886).
Dicellomus appalachia.

- 118 (same horizon as 117c). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales on the Tazewell road, 2 miles (3.2 km.) north of Knoxville, Knox County, Tenn. (M. R. Campbell, 1891).
Obolus lamborni minimus.
119. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone in various localities in Jefferson and Hawkins counties, Tenn. (Ira Sayles, 1885).
Dicellomus appalachia.
121. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Rogersville shale, road just east of Harlan Knob, 4 miles (6.4 km.) northeast of Rogersville [see Keith, 1905, areal geology sheet], Hawkins County, Tenn. (C. D. Walcott, 1891).
Micromitra alabamaensis.
Obolus lamborni.
Obolus willisi.
Lingulella desiderata.
- | |
|---------------------------------------------------------------------------|
| Acrotreta rudis. *Billingsella? appalachia. *Wimanelia harlanensis. |
|---------------------------------------------------------------------------|
- 121a (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales on road leading from southeast of Harlan Knob to Amis post office, about 4 miles (6.4 km.) northeast of Rogersville [see Keith, 1905, areal geology sheet], Hawkins County, Tenn. (C. D. Walcott, 1891).
Micromitra alabamaensis.
122. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shale southwest of "Town Knobs",^a 1 mile (1.6 km.) southwest of Rogersville, Hawkins County, Tenn. (C. D. Walcott, 1891).
Obolus willisi.
Lingulella desiderata.
- 122a. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shale at the headwaters of Forgey Creek, northwestern part of the Greeneville quadrangle (U. S. G. S.), Hawkins County, Tenn. (C. D. Walcott, 1891).
Obolus lamborni.
Lingulella desiderata.
123. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Upper part of Maryville limestone on Big Creek, southeast of Harlan Knob, 4 miles (6.4 km.) northeast of Rogersville [see Keith, 1905, p. 4, and areal geology sheet], Hawkins County, Tenn. (C. D. Walcott, 1891).
Micromitra alabamaensis.
Ptychoparia.
- 124 (=124a). (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales (Nolichucky?) overlying the limestone which rests on the Rogersville shale on Big Creek, southeast of Harlan Knob, 4 miles (6.4 km.) northeast of Rogersville [see Keith, 1905, p. 4, and areal geology sheet], Hawkins County, Tenn. (C. D. Walcott, 1891).
Micromitra alabamaensis.
Obolus lamborni minimus.
- 124a (=124). (For stratigraphic position and association, see p. 147.) (C. D. Walcott, 1891).
Obolus lamborni.
Lingulella (Lingulepis) acuminata.
Dicellomus appalachia.
128. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shale 1.5 miles (2.4 km.) southwest of Cleveland, Bradley County, Tenn. (C. D. Walcott, 1891).
Lingulella?
- 128a. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales on the Louisville and Nashville Railroad, 1.5 miles (2.4 km.) southeast of Cog Hill, near the line between Polk and McMinn counties, Tenn. (M. R. Campbell, 1891).
Lingulella sp.
Dicellomus politus.
131. Upper Cambrian: Sandstone in a cut on the Chicago, Milwaukee and St. Paul Railway, 4 miles (6.4 km.) southeast of Lake City, Wabasha County, Minn. (C. Schuchert, 1893).
Billingsella coloradoensis.
134. Upper Cambrian: "St. Croix sandstone" in the lowest beds exposed along the banks of Red Cedar River, opposite Menomonie, Dunn County, Wis. (C. Schuchert, 1893).
Obolus matinalis.

^a See localities 103, 103a, and 103b, pp. 220-221.

- 134a. Upper Cambrian: "St. Croix sandstone" in a quarry 1 mile (1.6 km.) southeast of the county courthouse, in Menomonie, Dunn County, Wis. (C. Schuchert, 1893).
Syntrophia barabuensis.
135. Upper Cambrian: "St. Croix sandstone" near Trempealeau, Trempealeau County, Wis. (C. Schuchert, 1893).
Lingulella winona convexa.
- 135b. Upper Cambrian: "St. Croix sandstone" near Trempealeau, Trempealeau County, Wis. (C. Schuchert, 1893).
Finkelnburgia finkelnburgi.
- 135c (=83¹). Upper Cambrian: Uppermost horizon of the "St. Croix sandstone" near Trempealeau, Trempealeau County, Wis. (C. Schuchert, 1893).
Finkelnburgia finkelnburgi.
Finkelnburgia osceola.
Dikellocephalus minnesotensis Owen.
136. Upper Cambrian: Potsdam sandstone in bank of stream opposite the first switch on the Port Henry and Maine Railroad out of Port Henry, Essex County, N. Y. (C. D. Walcott, 1889).
Lingulella prima.
137. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales on southeast side of northeast end of Cane Creek Mountains, 3 miles (4.8 km.) south of Gadsden, Etowah County, Ala. (Cooper Curtice, 1892).
Acrotreta kutorgai.
138. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shale in the street northeast of Printuf House, Gadsden, Etowah County, Ala. (Cooper Curtice, 1892).
Lingulella similis.
- 138a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales in the Rome formation west of the cemetery west of Rome, Floyd County, Ga. (Cooper Curtice, 1892).
Lingulella similis.
139. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone on Hokes Bluff road north of the chert outcrop, 5 miles (8 km.) east of Gadsden, Etowah County, Ala. (Cooper Curtice, 1892).
Lingulella desiderata.
- 139a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone on road near Wades Gap, near Chepultepec, Jefferson County, Ala. (Cooper Curtice, 1892).
Acrotreta kutorgai.
140. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone interbedded in shales near Chepultepec, Jefferson County, Ala. (Cooper Curtice, 1892).
Acrotreta kutorgai.
- 140a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales 200 yards (182.9 m.) east of Thomas Mills, 5 miles (8 km.) north of Cave Spring [see Hayes, 1902, historical geology sheet], Floyd County, Ga. (Cooper Curtice, 1892).
Obolus lamborni.
Obolus willisi.
Lingulella quadrilateralis.
- 140c. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shale at edge of hill on the road leading west of Cave Spring, 10 miles (16.1 km.) southwest of Rome, Floyd County, Ga. (Cooper Curtice, 1892).
Lingulella similis.
Lingulella sp.
- 141a. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone 0.25 mile (0.4 km.) west of the hotel at Montevallo, Shelby County, Ala. (Cooper Curtice, 1892).
Obolus (*Westonia*) *ella*.
142. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales just above the *Olenellus* zone near the railroad 4.5 miles (7.2 km.) north of Montevallo, Shelby County, Ala. (Cooper Curtice, 1892).
Acrotreta kutorgai?

- 144c.** (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone near the top of the beds exposed near N. K. Burns's barns, near Viola, Blount County, Ala. (Cooper Curtice, 1892).
Dicellomus appalachia.
- 145.** (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shale in bluff on Coosa River east of Turkeytown, 8 miles (12.8 km.) northeast of Gadsden, Etowah County, Ala. (Biddle and Russell, 1886).
Lingulella similis.
- 146.** (For stratigraphic position and association, see p. 147.) Middle Cambrian: Conasauga ("Coosa") shale on the Jacksonville road, 8 miles (12.8 km.) east of Center, Cherokee County, Ala. (Biddle, 1883).
Obolus willisi.
- 147a.** Upper Cambrian: Limestone in Spring Hill Canyon, west side of the Bridger Range, Gallatin County, Mont. (A. C. Peale, 1885).
Billingsella coloradoensis.
- 148a.** Upper Cambrian: Limestone of the Gallatin formation at the head of Bostwick Canyon (the name is given on the Threeforks sheet (U. S. G. S.)) [Iddings and Weed, 1894, areal geology sheet ^a, in the Bridger Range, Livingston quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1885).
Obolus tetonensis.
- 149a.** Middle Cambrian: Limestone at the forks of Pole Creek, above Cherry Creek basin, Threeforks quadrangle (U. S. G. S.), Madison County, Mont. (A. C. Peale, 1887).
Micromitra (Iphidella) pannula.
**Billingsella striata*.
- 150a.** Upper Cambrian: Limestone on the east side of Dry Creek, above the mouth of Pass Creek, about 5 miles (8 km.) north of Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1885).
Billingsella plicatella.
Eoorthis wichitaensis.
- 151** (see 151a). Upper Cambrian: Limestone in point overlooking Churn Canyon, on the west side of the Bridger Range, Gallatin County, Mont. (A. C. Peale, 1885).
Obolus discoideus.
Billingsella plicatella.
Eoorthis wichitaensis.
- 151a** (a little higher horizon than 151, same locality). Upper Cambrian: Limestone in point overlooking Churn Canyon, on the west side of the Bridger Range, Gallatin County, Mont. (A. C. Peale, 1885).
Dicellomus pectenoides.
Billingsella plicatella.
- 152.** Upper Cambrian: Limestone on ridge between Churn and Cottonwood canyons, west side of Bridger Range, Gallatin County, Mont. (A. C. Peale, 1885).
Billingsella plicatella.
Eoorthis desmopleura?
- 152a.** Upper Cambrian: Limestone on west side of Dry Creek, below Pass Creek, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1885).
Dicellomus nanus.
- 152b.** Upper Cambrian: East side of Dry Creek, below Pass Creek, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1885).
Obolus tetonensis?
- 153** (slightly different horizon than 153a). Upper Cambrian: Limestone in ravine on west side of Dry Creek, near the mouth of Pass Creek, about 5 miles (8 km.) north of Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1885).
Billingsella plicatella.
Huenella abnormis.
- 153a** (slightly different horizon than 153). Upper Cambrian: Limestone in ravine on west side of Dry Creek, near the mouth of Pass Creek, about 5 miles (8 km.) north of Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1885).
Eoorthis remnicha.
Eoorthis remnicha texana.
Eoorthis wichitaensis.

^a Iddings, J. P., and Weed, W. H., Livingston folio (No. 1), Geol. Atlas U. S., U. S. Geol. Survey, 1894.

154. Upper Cambrian: Limestone in hill on west side of Dry Creek, opposite mouth of Pass Creek, about 5 miles (8 km.) north of Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1885).
Billingsella plicatella.
Eoorthis desmopleura?.
Eoorthis remnicha.
155. Upper Cambrian: Limestone north of East Gallatin River, near Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1888).
Billingsella coloradoensis.
- 155a. Middle Cambrian: Limestone north of East Gallatin River, near Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1888).
 **Micromitra pealei*.
- 156a. Middle Cambrian: Limestones of the Flathead formation [Peale, 1893, p. 20], north of East Gallatin River, near Hillsdale, Gallatin County, Mont. (A. C. Peale, 1888).
Acrotreta attenuata.
- 156b. Upper Cambrian: Limestone north of East Gallatin River, at the north end of the Gallatin Valley, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1884).
Billingsella plicatella.
- 157 (same locality as 156 and 156b, but different horizon). Upper Cambrian: Limestone north of East Gallatin River, near Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1888).
Billingsella plicatella.
Huenella abnormis.
- 158 (same locality as 156, 157, and 158a, but different horizon). Upper Cambrian: Limestone north of East Gallatin River, near Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1889).
Dicellomus pectenoides.
 **Billingsella plicatella*.
 | *Eoorthis desmopleura*.
 | *Huenella abnormis*.
- 158a (same locality as 156, 157, and 158, but different horizon). Upper Cambrian: Limestone north of East Gallatin River, near Hillsdale, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1889).
Dicellomus nanus.
159. Middle Cambrian: Limestones north of West Gallatin (Gallatin) River, Gallatin County, Mont. (A. C. Peale, 1884).
Micromitra pealei.
Obolus rotundatus.
Acrotreta attenuata.
 | *Billingsella coloradoensis*.
 | *Olenoides?*.
160. Upper Cambrian: Sandstones forming a remnant of the Gallatin formation which lies between the exposures of "porphyrite" on the east side of Willow Creek [Peale, 1896, areal geology sheet], 12 miles (19.2 km.) south-southwest of Threeforks, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1889).
Micromitra (Paterina) superba?.
- 160a. Upper Cambrian: Sandstone west of Bear Creek, south of the Gallatin Valley southwest of Bozeman, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale, 1889).
Obolus rotundatus.
161. Upper Cambrian: Limestone on the south side of West Gallatin (Gallatin) River, northwest of Hamilton on the north side of the Gallatin Valley, Gallatin County, Mont. (A. C. Peale, 1884).
Obolus tetonensis.
Lingulella desiderata.
- 163 (=55c). (For stratigraphic position and association, see p. 152.) (R. S. Spence.,
Micromitra (Iphidella) pannula.
Acrothele subsidua.
 **Acrotreta definita*.
 | **Nisusia (Jamesella) nautes*.
 | **Nisusia (Jamesella) spencei*.
164. Middle Cambrian: Sandstone in the Deadwood formation in the cliffs on the east side of the valley near Deadwood, Black Hills, South Dakota.
Dicellomus pectenoides.
- 164f. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales just above a bed of limestone on the road leading northwest out of Montevallo, Shelby County, Ala.
Obolus? sp.

165. Middle Cambrian: Limestone on the east side of the valley, in railroad cut about 1 mile (1.6 km.) below the main part of Deadwood, Black Hills, South Dakota.
Lingulella similis.
Acrotreta idahoensis.
Linnarssonella girtyi.
167. Middle Cambrian: Sandstone beneath limestone and resting on pre-Cambrian "slates, schists, and pegmatites" in bluff 9 miles (14.4 km.) west of Custer, Black Hills, South Dakota.
Lingulella cuneola?
Lingulella (Lingulepis) acuminata.
Dicellomus politus.
168. Upper Cambrian: Limestones on north side of Tepee Creek, near the road from Sheridan to Dome Lake, Bighorn Mountains, Sheridan County, Wyo. (C. D. Walcott).
Eoorthis desmopleura. | *Eoorthis remnicha*.
 **Eoorthis desmopleura nympha*. | *Syntrophia primordialis*.
170. Middle Cambrian: Sandstone about 10 miles (16.1 km.) south-southeast of Bald Mountain, Bighorn Mountains, Wyo.
Obolus matinalis.
Dicellomus nanus.
- 171 (200 feet below 171a). Middle Cambrian: Sandstone in Big Goose Creek Canyon, in the Bighorn Mountains, west of Sheridan, Sheridan County, Wyo.
Lingulella (Lingulepis) acuminata (ranging through 200 feet of beds).
- 171a (200 feet above 171). Middle Cambrian: Sandstone in Big Goose Creek Canyon, in the Bighorn Mountains, west of Sheridan, Sheridan County, Wyo.
Obolus (Westonia) ella.
Lingulella (Lingulepis) acuminata.
- 174c. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Sandstones on small hill in the salt flat 1 mile (1.6 km.) northeast of Silver Peak mill, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (C. D. Walcott and F. B. Weeks, 1896).
 **Mickwitzia occidens*.
Obolus?
Obolella sp.
175. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Shales carrying *Olenellus* on the divide between Clayton and Fish Lake valleys, about 15 miles (24.2 km.) south-southwest of the town of Silver Peak, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (C. D. Walcott and F. B. Weeks, 1896).
Obolus? | **Acrotreta claytoni*.
Kutorgina perugata? | *Swantonina?* sp.
176. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Shales and interbedded limestones between massive limestone containing *Archæocyathus*, at the south end of Deep Spring Valley, Inyo County, Cal. (C. D. Walcott and F. B. Weeks, 1896).
Obolella vermilionensis. | *Wanneria gracile* Walcott.
Obolella? sp. | *Olenellus fremonti* Walcott.
Trematobolus excelsis.
- 176a. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Sandstone on ridge east of the head of Mazouka Canyon, Inyo Range, Inyo County, Cal. (C. D. Walcott, 1897).
Trematobolus excelsis.
- 178a (slightly higher than 176, but same locality). (For stratigraphic position and association, see p. 138.) (C. D. Walcott and F. B. Weeks, 1896).
Trematobolus excelsis. | *Wanneria gracile* Walcott.
Billingsella highlandensis? | *Olenellus fremonti* Walcott.
184. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Shales at the summit of the Silver Peak Range, 10 miles (16.1 km.) southwest of the town of Silver Peak, Silver Peak quadrangle (U. S. G. S.), Esmeralda County, Nev. (C. D. Walcott, 1896).
Kutorgina perugata.
Acrotreta claytoni.

185. Upper Cambrian: Sandy layers above the massive Potsdam sandstone 0.5 mile (0.8 km.) southeast of Redwood, Jefferson County, N. Y. (C. D. Walcott, 1886).
Lingulella (*Lingulepis*) acuminata.
- 185a. Upper Cambrian: Sandy layers 20 feet (6 m.) above the massive Potsdam sandstone, east side of Indian View, 3 miles (4.8 km.) south of Theresa, Jefferson County, N. Y. (C. D. Walcott, 1886).
Lingulella (*Lingulepis*) acuminata.
- 185z. (For stratigraphic position and association, see p. 148.) Lower Ordovician: Limestones at the base of the Lower Ordovician [Walcott, 1908f, p. 191], in Blacksmith Fork Canyon, about 9 miles (14.4 km.) east of Hyrum, Cache County, Utah (C. D. Walcott and L. D. Burling, 1906).
Obolus discoideus. | Orthoceras.
Eoorthis desmopleura. | Endoceras.
Syntrophia nundina. | Fragments of trilobites.
186. Lower Ordovician: Near line of contact between red and gray Ordovician limestone, in red siliceous limestone about 30 feet (9.1 m.) above the pre-Cambrian rocks, Williams Canyon, Manitou, El Paso County, Colo. (C. D. Walcott, 1890).
Lingulella desiderata. | Eoorthis desmopleura nympha.
Schizambon manitouensis. | Syntrophia nundina.
Eoorthis desmopleura.
- 186a (slightly higher horizon than 186). Lower Ordovician: Near line of contact between red and gray Ordovician limestone, in siliceous red limestone about 35 feet (10.7 m.) above the pre-Cambrian rocks, Williams Canyon, Manitou, El Paso County, Colo. (T. W. Stanton, 1890).
*Schizambon manitouensis.
Eoorthis desmopleura.
Syntrophia nundina.
187. Lower Ordovician: Red siliceous limestone 105 to 122 feet (32 to 36.7 m.) above the pre-Cambrian rocks, 2 miles (3.2 km.) below Manitou Park Hotel, El Paso County, Colo. (Whitman Cross, 1882).
Lingulella desiderata.
Eoorthis desmopleura.
201. (For stratigraphic position and association, see p. 139.) Passage beds between the Upper Cambrian and the Ordovician: Arenaceous Pogonip limestone on east slope of ridge east of Hamburg Ridge Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (Arnold Hague and C. D. Walcott, 1880).
*Lingulella pogonipensis.
Acrotreta idahoensis alta.
Eoorthis hamburgensis.
- 201a. (For stratigraphic position and association, see p. 139.) Lower Ordovician: Pogonip limestone, east slope of the ridge east of Hamburg Ridge, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1882).
*Obolus (*Westonia*) iphis. | Acrotreta idahoensis.
Lingulella pogonipensis. | Eoorthis hamburgensis.
*Schizambon typicalis. | Syntrophia nundina.
Acrothele sp. | Agnostus prolongus Hall and Whitfield.
202. (For stratigraphic position and association, see p. 139.) Lower Ordovician: Pogonip limestone on the summit of the ridge directly southeast of the Jackson mine, northwest of Shadow Canyon, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).
Lingulella manticula. | Elkania ambigua.
Lingulella sp. | Acrotreta idahoensis.
203. (For stratigraphic position and association, see p. 139.) Lower Ordovician: Pogonip limestone on spur of Hamburg Ridge extending out southwest from Wood Cone, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).
Syntrophia nundina.
Bathyurus congeneris Walcott.
Bathyurus tuberculatus Walcott.
- 203a. (For stratigraphic position and association, see p. 139.) Passage beds between the Upper Cambrian and the Ordovician: Limestones at base of Pogonip limestone in the spur of Hamburg Ridge extending out southwest from Wood Cone, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).
Lingulella pogonipensis.
*Acrotreta curvata.
Agnostus tumidosus Hall and Whitfield.

204. (For stratigraphic position and association, see p. 139.) Lower Ordovician: Pogonip limestone on the lower part of the eastern slope of the ridge east of Hamburg Ridge, facing Secret Canyon road, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

**Syntrophia nundina*.

205. (For stratigraphic position and association, see p. 139.) Passage beds between the Upper Cambrian and the Ordovician: Siliceous limestone on Roundtop Mountain, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (Arnold Hague and J. P. Iddings, 1880).

Obolus mæra.

**Obolus* (*Westonia*) sp. undt. b.

Lingulella pogonipensis.

**Acrotreta?* *cancellata*.

Eoorthis hamburgensis.

- 206a. (For stratigraphic position and association, see p. 139.) Passage beds between the Upper Cambrian and the Ordovician: Sandy limestone on Hoosac Mountain, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

Acrotreta idahoensis alta.

209. (For stratigraphic position and association, see p. 139.) Lower Ordovician: Pogonip limestone on the west side of Goodwin Canyon, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (C. D. Walcott, 1880).

Syntrophia nundina.

211. (For stratigraphic position and association, see p. 139.) Passage beds between the Upper Cambrian and the Ordovician: Siliceous Pogonip limestone on spur of Hamburg Ridge extending southwest from Wood Cone, Eureka district [Hague, 1892, Atlas], Eureka County, Nev. (Arnold Hague, J. P. Iddings, and C. D. Walcott, 1880).

Lingulella pogonipensis.

- 214a (see 313k). (For stratigraphic position and association, see p. 139.) Ordovician: Near the base of the Pogonip limestone, White Pine district, White Pine County, Nev. (C. D. Walcott and C. H. H., 1882).

**Obolus* sp. undt. c.

- 214b (see 313k). (For stratigraphic position and association, see p. 139.) Lower Ordovician: Limestones near the middle of the Pogonip limestone, White Pine district, White Pine County, Nev. (C. D. Walcott and C. H. H., 1882).

Lingulella manticula.

- 216a. Ordovician: Limestone at Fossil Butte, 10 miles north of Hyko, Lincoln County, Nev. (C. D. Walcott, 1885).

Huenella sp.

- 220a. Ordovician: Shales of the "Upper Sillery" (Lauzon of Logan) on Chaudiere River, at the Grand Trunk Railroad bridge, Province of Quebec, Canada (C. D. Walcott, 1889).

**Lingulella ellsii*.

**Acrothele pretiosa*.

221. (For stratigraphic position and association, see p. 139.) Ordovician: Pogonip limestone, below the white quartzite, at the western base of Lone Mountain, Keyes Valley, 18 miles (28.8 km.) northwest of Eureka, Eureka County, Nev. (C. D. Walcott, 1880).

Acrotreta sp. undt.

227. Lower Ordovician: Limestone near Fort Cassin, Addison County, Vt. (W. P. Rust, 1887).

**Syntrophia lateralis*.

Localities 300-396z, arbitrarily numbered.^a

- 300 [Matthew, 1886, p. 37]. (For stratigraphic position and association, see p. 132.) Middle Cambrian: Shaly sandstones, possibly of Division 1d of Matthew, on Long Reach, St. John River, Kings County, New Brunswick.

**Acrotreta baileyi* Matthew.

Ptychoparia robbi? (Hartt).

- 301 (references follow species; see 2h). (For stratigraphic position and association, see p. 133.) Middle Cambrian: In sandstones of Division 1b2 of the "*Protolenus* zone" [Matthew, 1895a, p. 108], on Hanford Brook, St. John County, New Brunswick.

Acrothele matthewi lata [Matthew, 1886, p. 42].

Acrotreta baileyi? [Matthew, 1886, p. 37].

Acrotreta gemmula [Matthew, 1895a, p. 126].

**Trematobolus insignis* [Matthew, 1895a, p. 123].

**Trematobolus pristinus* [Matthew, 1895a, p. 122].

**Beyrichona papilio* [Matthew, 1886, p. 66].

**Beyrichona tineia* [Matthew, 1886, p. 66].

^a See the explanatory paragraphs on pp. 160-161.

- 301a** (references follow species). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Fine-grained sandstones below the *Protolenus*-bearing shales and sandstones in Division 1b3 of Matthew, Hanford Brook, St. John County, New Brunswick.
- **Acrothele matthewi lata* [Matthew, 1895a, Pl. V, fig. 8]. | **Diplothea acadica crassa* [Matthew, 1886, p. 55].
Acrothele matthewi prima [Matthew, 1895a, Pl. V, fig. 7]. | **Diplothea hyattiana* [Matthew, 1886, p. 52].
 **Acrotreta gemmula* [Matthew, 1894, p. 88]. | **Agraulos? articephalus* [Matthew, 1886, p. 75].
- 301b** [Matthew, 1895a, p. 126]. (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstones of Division 1b5 and higher of the "*Protolenus zone*" [Matthew, 1895a, p. 108], Hanford Brook, St. John County, New Brunswick.
Acrotreta sagittalis transversa.
- 301c** [Walcott, 1884a, p. 16]. (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstones of the St. John formation at Coldbrook, St. John County, New Brunswick.
 **Acrotreta sagittalis transversa*.
Acrotreta sp.
- 301d** [Matthew, 1895a, p. 128]. (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstones of Division 1b5 of Matthew, on Hanford Brook, St. John County, New Brunswick.
Acrothele prima costata.
- 301e** [Matthew, 1903, p. 204]. (For stratigraphic position and association, see p. 131.) Upper Cambrian: In Division C3a of Matthew, in the St. John Basin, St. John County, New Brunswick.
Lingulella cf. lepis.
- 301f** [Matthew, 1905a, p. 128]. (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstones of Division 1b5 of the "*Protolenus zone*" of Matthew, at Catons Island, in Long Reach, St. John River, Kings County, New Brunswick.
Acrothele prima costata.
- 301g** (references follow species: see 301w, 308h, and 308i). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Sandstones of Division 1c of Matthew, at Portland (now part of the city of St. John), St. John County, New Brunswick.

Microdiscus punctatus pulchellus [U. S. National Museum and Matthew, 1886, p. 75].
**Paradoxides abenacus* [Matthew, 1886, p. 80].
**Solenopleura acadica* [Matthew, 1886, p. 77].
- 301m** (references follow species). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Shale of Division 1c of Matthew's section on Porters Brook, St. Martins, St. John County, New Brunswick.
- Protorthis quacoensis* [Matthew, 1886, p. 44].
**Stenothecca radiata* [Matthew, 1886, p. 58].
- Hyolithes (Camerototheca) danianus* [Matthew, 1886, p. 50].
Eocoryne geminum (U. S. National Museum).
- 301n** [Matthew, 1892, p. 39]. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales of Division 3a of Matthew, on the "right shore," below the "falls," St. John Harbor, St. John County, New Brunswick.
- *Lingulella laevis*.
- 301s** [Matthew, 1894, p. 91]. Lower Ordovician: Gray sandstones of Division 3e (?) of Matthew, at McAphee's Corner, Hardingville, St. John County, New Brunswick.
- *Lingulella grandis*.
- 301t** [Matthew, 1903, p. 201]. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Sandy shales of Division C3a of Matthew, at Carlton shore, near the suspension bridge, St. John, St. John County, New Brunswick.
- Lingulella laevis grandis*.
- 301u** (references follow species). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales of Division C3h of Matthew, in the St. John Basin, St. John County, New Brunswick.
- Lingulella cf. lepis* [Matthew, 1903, p. 204].
Sphaerophthalmus alatus [Matthew, 1903, p. 240].

301v [Matthew, 1890, p. 155]. Lower Cambrian: Sandy shales of Division 2b of the "basal series" of Matthew, on Hanford Brook, St. John County, New Brunswick.

**Rustella major*.

The following species were found at the same locality and approximate horizon [Walcott, 1900, p. 322]:

Micromitra (*Paterina*) *labradorica*.

Hyalolithes cf. *communis*.

Coleoloides cf. *typicalis*.

301w (references follow species; see 301g, 308h, and 308i). (For stratigraphic position and association, see p. 132.)

Middle Cambrian: Shales of Division 1c2 of Matthew's section at Portland (now part of the city of St. John), St. John County, New Brunswick.

Discinopsis gulielmi (U. S. National Museum).

Acrothele matthewi (U. S. National Museum).

**Protorthis latourensis* [U. S. National Museum and Matthew, 1886, pp. 42 and 82].

Protorthis quacoensis (U. S. National Museum).

Hyalolithes (*Camerothera*) *micmac* [Matthew, 1886, p. 81].

Stenotheca triangularis [Matthew, 1886, pp. 58 and 83].

Stenotheca (*Parmophorella*) *acadica* [Matthew, 1886, p. 60].

Agnostus regulus [Matthew, 1886, pp. 68 and 84].

Microdiscus dawsoni [Matthew, 1886, pp. 75 and 84].

Paradoxides acadicus suricus [Matthew, 1886, p. 78].

Paradoxides etemicus (U. S. National Museum).

Ctenocephalus matthewi (U. S. National Museum).

Ctenocephalus matthewi hispidus (U. S. National Museum).

Ptychoparia (*Liostracus*) *ouangondiana* (U. S. National Museum).

Conocoryphe (*Bailiella*) *baileyi* (U. S. National Museum).

Conocoryphe (*Bailiella*) *baileyi arcuata* (U. S. National Museum).

Conocoryphe (*Bailiella*) *walcotti* (U. S. National Museum).

301x [Matthew, 1891, p. 148, and on label with the specimens in Matthew's collection]. (For stratigraphic position and association, see p. 131.) Middle Cambrian: Sandstones of Division C2c of Matthew, Dunns Shore, Simonds, near St. John, St. John County, New Brunswick.

Lingulella radula aspera = *Lingulella radula*.

301y [Matthew, 1891, p. 148, and Museum of Comparative Zoology]. For stratigraphic position and association, see p. 131.) Middle Cambrian: Shaly sandstones of Division C2c of Matthew, east side of Courtney Bay, St. John, New Brunswick.

**Lingulella radula aspera* = *Lingulella radula*.

301z (references follow species). (For stratigraphic position and association, see p. 132.) Middle Cambrian: Division 1c of Matthew, on Ratcliffs Millstream, St. John County, New Brunswick.

Lingulella dawsoni [Matthew, 1886, p. 34] = *Lingulella ferruginea*.

Hartia matthewi [Matthew, 1886, p. 61].

Hyalolithes (*Camerothera*) *danius* [Matthew, 1886, p. 50].

Conocoryphe (*Bailiella*) *elegans* (U. S. National Museum).

302 [U. S. National Museum]. Middle Cambrian: Limestone east of West Gallatin (Gallatin) River, above Gallatin, Gallatin County, Mont.

Micromitra pealei.

**Micromitra sculptilis*.

Obolus matinalis.

**Acrotreta attenuata*.

**Acrotreta attenuata* var.

Eoorthis hamburgensis.

Eoorthis sp.

302a [U. S. National Museum]. Middle Cambrian: Limestones at several places on the south side of Gallatin Valley, Gallatin County, Mont.

Micromitra sculptilis.

Acrotreta idahoensis.

302b [U. S. National Museum]. Middle Cambrian: Limestones near Crowfoot Ridge, Gallatin quadrangle (U. S. G. S.), Yellowstone National Park, Wyo.

Micromitra sculptilis.

**Micromitra* sp. undt.

Obolus rotundatus.

Lingulella desiderata.

Lingulella sp.

**Lingulella* (*Lingulepis*) *acuminata meeki*.

Dicellomus nanus.

Acrotreta idahoensis.

Eoorthis remnicha.

These species may not all be from the same bed or from exactly the same locality.

302c [U. S. National Museum]. Upper Cambrian: Shaly limestone on south side of Gallatin Valley, Yellowstone National Park, Wyo.

Micromitra sculptilis.

**Eoorthis iddingsi*.

- 302d** [U. S. National Museum]. Upper Cambrian: Limestone 200 yards (183 m.) north of the southwest corner of sec. 18, T. 28 N., R. 113 W., Uinta County, Wyo. (E. E. Smith).
Obolus matinalis.
Obolus sinoc.
Eoorthis iddingsi.
- 302e** [U. S. National Museum]. Upper Cambrian: Limestone near the top of the Deadwood formation in Big Popo Agie Canyon, near Lander, Fremont County, Wyo. (N. H. Darton).
Eoorthis wichitaensis.
- 302f** [U. S. National Museum]. Upper Cambrian: Upper part of the Gallatin formation, north side of Elk Pass, between Buffalo and Slough creeks, Yellowstone National Park, Livingston quadrangle (U. S. G. S.), Mont.
Billingsella coloradoensis.
Otusia sandbergi.
- 302g** [U. S. National Museum]. Upper Cambrian: Limestone on the north slope of Crowfoot Ridge, south of the Gallatin Valley, Gallatin quadrangle (U. S. G. S.), Yellowstone National Park, Wyo.
Billingsella coloradoensis.
- 302h** [U. S. National Museum]. Upper Cambrian: Limestone on the divide between Panther Creek and Gallatin River, Gallatin quadrangle (U. S. G. S.), Yellowstone National Park, Wyo.
Billingsella coloradoensis.
- 302j** [U. S. National Museum records]. Lower Ordovician: Limestone on the east side of West Gallatin (Gallatin) River, above Gallatin, Gallatin County, Mont.
Obolus matinalis.
 **Clarkella montanensis*. } These species may not be from the same exact locality.
- 302k** [U. S. National Museum]. Middle Cambrian: Limestone near Gallatin, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont.
Dicellomus politus.
- 302l** [U. S. National Museum]. Middle Cambrian: Limestone in the Gallatin Range, Yellowstone National Park, Wyo.
 **Lingulella desiderata*.
- 302m** [U. S. National Museum]. Middle Cambrian: Middle of shale above lower sandstone on Billy Creek, in the Bighorn Mountains, Sheridan County, Wyo. (N. H. Darton, 1902).
Lingulella (Lingulepis) acuminata.
Dicellomus nanus.
- 302n** [U. S. National Museum]. Upper Cambrian: Limestone on the south side of the Gallatin Valley, Gallatin County, Mont.
Eoorthis remnicha.
- 302o** [U. S. National Museum]. Middle Cambrian: Sandstones just above the granite west of Garfield Peak, 50 miles (80.5 km.) west of Casper, Natrona County, Wyo. (N. H. Darton).
 **Obolus (Westonia) dartoni*.
- 302p** [U. S. National Museum]. Upper Cambrian: Middle limestone of the Deadwood formation near the summit of the Owl Creek Mountains, 18 miles (29 km.) southwest of Thermopolis, Fremont County, Wyo. (N. H. Darton).
Billingsella coloradoensis.
Huenella abnormis.
Ptychoparia.
- 302q** [U. S. National Museum]. Upper Cambrian: About 1,000 feet (305 m.) above the quartzitic sandstones in the "Yogo limestone (Devono-Silurian)" of W. H. Emmons [1907, p. 34], on Rock Creek, Phillipsburg quadrangle (U. S. G. S.), Granite County, Mont. (E. M. Kindle, 1907).
Billingsella coloradoensis.
- 302r** [U. S. National Museum]. Upper Cambrian: About 1,000 feet (305 m.) above the quartzitic sandstones in the "Yogo limestone (Devono-Silurian)" of W. H. Emmons [1907, p. 34], near Princeton, Phillipsburg quadrangle (U. S. G. S.), Granite County, Mont. (E. M. Kindle, 1907).
Obolus cf. discoideus.
Billingsella coloradoensis.
Cyrtolites.
- | *Agraulos*.
 | *Anomocare*.

- 302s** [U. S. National Museum]. Middle Cambrian: Dark siliceous shale in a quarry in Last Chance Gulch, south slope of Mount Helena, 1.5 miles (2.4 km.) south of Helena, Jefferson County, Mont.
Obolus (*Westonia*) *ella*.
 **Lingulella helena*.
Dicellomus politus.
- 302t** [U. S. National Museum]. Middle Cambrian: Limestone northeast of Logan, Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont.
Micromitra (*Iphidella*) *pannula*.
Acrotreta sp. undt.
Ptychoparia.
- 302u** [U. S. National Museum]. Upper Cambrian: Upper limestone of the Deadwood formation north of Cheever's ranch, on the summit of the Bighorn Mountains, Wyo. (N. H. Darton).
Dicellomus nanus.
- 302v** [U. S. National Museum]. Ordovician: Sandstones 2 miles (3.2 km.) west of the main summit of Buffalo Fork Peak [see St. John, 1877, pp. 468 and 469 and map opposite p. 324 (near station XLIX)], about 25 miles (40 km.) east of Jackson Lake, Uinta County, Wyo.
Dicellomus nanus.
- 302w** [U. S. National Museum]. Middle Cambrian: Limestone at Madison Mountain, Mont.
Acrotreta idahoensis.
Billingsella coloradoensis.
- 302x** [U. S. National Museum]. Middle Cambrian: Sandstones near the head of Powder River, Bighorn Mountains, Wyo. (F. V. Hayden).
Obolus sinoe.
- 302y** [U. S. National Museum]. Middle Cambrian: Sandstone on Johnson Creek, Bighorn Mountains, Wyo. (N. H. Darton, 1902).
Dicellomus nanus.
- 302z** [U. S. National Museum]. Middle Cambrian: Limestone on Mill Creek, near Landusky, Little Rocky Mountains, Chouteau County, Mont. (W. H. Weed).
Dicellomus nanus.
- 303** [Barrande, 1879b, Pl. XCV]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d3 at Königshof, Bohemia, Austria-Hungary.
 **Acrotreta babel*.
- 303a** (references follow species). (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d3 at Trubin, Bohemia, Austria-Hungary.
Lingulella? *simplex* [Barrande, 1879b, Pl. CIV].
Acrotreta babel? [Barrande, 1879b, Pl. XCV].
- 303b** [Barrande, 1879b, Pl. CXXVI]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 in the environs of Rokitzan, Bohemia, Austria-Hungary.
 **Obolus?* *rokitzanensis*.
- 303c** (references follow species). (For stratigraphic position and association, see p. 124.) Passage beds between the Upper Cambrian and the Ordovician: Suburbs of Hof, Bavaria, Germany.
 **Obolus?* *bavaricus* [Barrande, 1868a, p. 100].
 **Obolus?* *minor* [Barrande, 1868a, p. 105].
 **Obolus?* *palliatus* [Barrande, 1868a, p. 105].
 **Lingulella cedens* [Barrande, 1868a, p. 102].
 **Lingulella?* *humillima* [Barrande, 1868a, p. 101].
 **Lingulella signata* [Barrande, 1868a, p. 103].

| * <i>Lingulella wirthi</i> [Barrande, 1868a, p. 101]. * <i>Acrotreta inchoans</i> [Barrande, 1868a, p. 102]. * <i>Orbiculoidea contraria</i> [Barrande, 1868a, p. 104]. * <i>Orbiculoidea varians</i> [Barrande, 1868a, p. 103]. * <i>Eoorthis bavarica</i> [Barrande, 1868a, p. 99]. |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
- 303d** (references follow species). (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Swarow, Bohemia, Austria-Hungary.
 **Obolus?* *advenus* [Barrande, 1879b, Pl. XCV].
Lingulella? *insons* [Barrande, 1879b, Pl. CV].
 **Acrotreta?* *minima* [Barrande, 1879b, Pl. XCV].

303e [Barrande, 1879b, Pl. CV]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Sta. Benigna, Bohemia, Austria-Hungary.

*Lingulella? insons.

303f [Pompeckj, 1896a, pp. 7 and 8]. (For stratigraphic position and association, see p. 124.) Passage beds between the Upper Cambrian and the Ordovician: Railway cut near Schellenberg, a little distance back of the railway station at Neuohof, near Hof, Bavaria, Germany.

Lingulella cedens.

Lingulella? humillima.

Lingulella wirthi.

Lingula n. sp.

Acrotreta inchoans.

Acrotreta n. sp.

Orbiculoidea contraria.

Orbiculoidea varians.

Orthis sp.=Eoorthis bavarica.

Macrocystella bavarica.

Bellerophon n. sp.

Bavarilla hofensis.

Dikellocephalus (?) bavaricus.

Niobe innotata.

Niobe discrepans.

303g [Barrande, 1879b, Pl. CXI]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Rabenberg, Bohemia, Austria-Hungary.

*Obolus? ancillus.

Obolus? complexus.

303h [Barrande, 1879b, Pl. XCV]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Milinsky Wrch, near Woleschna, Bohemia, Austria-Hungary.

Obolus complexus.

303i (references follow species). (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Kruschna Hora, Bohemia, Austria-Hungary.

*Obolus complexus [Barrande, 1879b, Pl. XCV].

*Obolus feistmanteli [Barrande, 1879b, Pl. CX].

303j [Barrande, 1879b, Pl. CVI]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Czerhowitz, Bohemia, Austria-Hungary.

Obolus feistmanteli.

303k [Barrande, 1879b, Pl. CXI]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Hradischt, Bohemia, Austria-Hungary.

*Obolus? mirandus.

303l [Barrande, 1879b, Pl. CVI]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d1 at Libetschov, Bohemia, Austria-Hungary.

*Obolus? (Westonia?) lamellosus.

Lingula? eximia.

303m [Barrande, 1879b, Pl. CIV]. (For stratigraphic position and association, see p. 124.) Ordovician: Étage d4 at Lieben, Bohemia, Austria-Hungary.

*Lingulella davidsoni.

303n [Barrande, 1879b, Pl. CIV]. (For stratigraphic position and association, see p. 124.) Ordovician: Étage d4 at Wraž, Bohemia, Austria-Hungary.

Lingulella davidsoni.

303o [Barrande, 1879b, Pl. CIV]. (For stratigraphic position and association, see p. 124.) Ordovician: Étage d4 at Lodenitz, Bohemia, Austria-Hungary.

Lingulella davidsoni.

303p [Barrande, 1879b, Pl. CIV]. (For stratigraphic position and association, see p. 124.) Lower Ordovician: Étage d3 in the environs of Beraun, Bohemia, Austria-Hungary.

*Lingulella? simplex.

304 [Matley, 1902, p. 145]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: "Bronsil" shales at White Leaved Oak, Malvern Hills, between Herefordshire and Worcestershire, England.

Acrotreta belti.

- 304a** [Groom, 1902, p. 110]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: "Bronsil" shales, Malvern Hills, between Herefordshire and Worcestershire, England.
- | | |
|--------------------------------|-----------------------------------------|
| Obolus (Bröggeria) salteri. | (?) Hyolithes assulatus Groom. |
| Lingulella nicholsoni. | Agnostus dux Callaway. |
| Lingulella? sp. = Acrothyra?. | Cheirusus frederici Salter. |
| Lingula sp. | Platypeltis croftii Callaway?. |
| Acrotreta belti. | Asaphellus affinis McCoy?. |
| Acrotreta cf. nicholsoni. | Parabolinella (?) triarthrus Callaway?. |
| Acrotreta sabrinæ. | Acanthopleurella grindrodi Groom. |
| Acrotreta cf. socialis. | Niobe homfrayi Salter?. |
| Dictyonema sociale Salter. | (?) Niobe? sp., near O. peltata Salter. |
| Tomaculum problematicum Groom. | |
- 304b** [Groom, 1902, p. 109]. (For stratigraphic position and association, see p. 135.) (See 304f, the "black shales" being another name for the "White Leaved Oak shales"). Upper Cambrian: Lower part of the "White Leaved Oak" shales (the zone of *Polyphyma*), Malvern Hills, between Herefordshire and Worcestershire, England.
- | | |
|-------------------------------------|---------------------------------|
| Micromitra pusilla. | Small ostracod. |
| Lingulella nicholsoni (doubtfully). | Protospongia fenestrata Salter. |
| Acrotreta sabrinæ. | Plant remains (?). |
| Polyphyma lapworthi Groom. | Agnostus sp. |
- 304c** [Groom, 1902, p. 94]. (For stratigraphic position and association, see p. 136.) Lower Cambrian: "Malvern quartzite" at Raggedstone Hill, Malvern Hills, between Herefordshire and Worcestershire, England.
- | | |
|----------------------------------|---------------------------|
| Micromitra (Paterina) phillipsi. | Hyolithes fistula (Holl). |
| Obolella groomi. | Hyolithes primævus Groom. |
- 304d** [Groom, 1902, p. 94]. (For stratigraphic position and association, see p. 136.) Lower Cambrian: "Malvern quartzite" at Midsummer Hill, Malvern Hills, between Herefordshire and Worcestershire, England.
- Micromitra (Paterina) phillipsi.
- Obolella groomi.
- 304e** [Davidson, 1866, p. 62]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper part of the black "White Leaved Oak" shales at Coal Hill, east end of the Malvern Hills, between Herefordshire and Worcestershire, England.
- *Obolus (Bröggeria) salteri.
- 304f** [Salter, 1865, p. 102]. (For stratigraphic position and association, see p. 135.) (See 304b, the "black shales" being another name for the "White Leaved Oak shales.") Upper Cambrian: "Black shales" in the Malvern Hills, between Herefordshire and Worcestershire, England.
- *Lingulella (Lingulepis?) pygmaea.
- 304g** (references follow species). (For stratigraphic position and association, see p. 135.) Upper Cambrian: Sandstones of the Hollybush series (horizon of Middle *Lingula* beds [Davidson, 1866, p. 63]), Malvern Hills, between Herefordshire and Worcestershire, England.
- *Micromitra (Paterina) phillipsi [Holl, 1865, p. 89].
- *Lingulella (Lingulepis?) squamosa [Holl, 1865, p. 102].
- Groom [1902, p. 109] cites the following from the "Hollybush sandstones":
- | | |
|-------------------------------|-------------------------------------|
| Micromitra phillipsi. | Hyolithes, 2 or more species. |
| Acrotreta sagittalis?. | Coleoloides? sp. |
| Hyolithes fistula (Holl). | Scolecoderma antiquissima (Salter). |
| Hyolithes malvernensis Groom. | Modiolopsis? sp. |
| Hyolithes primævus Groom. | Foraminifera (glauconitic casts). |
- 304h** [U. S. National Museum]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Shineton shales, Mary Dingle, South Shropshire, England.
- Acrotreta nicholsoni.
- *Acrotreta sabrinæ.
- 304i** [Callaway, 1877, p. 669]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Shineton shale at Shineton, Mary Dingle, Dryton, Cressage, 1 mile (1.6 km.) west of Cressage, west of Harley, and under Cound-Moor quarry, all in South Shropshire, England.
- *Lingulella nicholsoni.
- Acrotreta sabrinæ.
- 304j** [Mason College collections]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Stockingford shales, Puxley Park Lane, halfway up the path to the quarry, Atherstone, Warwickshire, England (C. A. Matley, 1894).
- Acrothele intermedia?.
- Acrotreta sabrinæ.

- 304k** [Davidson, 1883, pp. 208 and 209]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Shineton shale at Bull Hill Cottage and Pewardine, both in South Shropshire, England.
Lingulella nicholsoni.
- 304l** [Geol. Survey Great Britain]. (See 304p.) (For stratigraphic position and association, see p. 135.) Upper Cambrian: Shineton shales at the following localities of the Geological Survey of Great Britain: 2246, 2481, 2499, 2512, 2513, 2541, 2548, 2556, 2567, 2625, and 2627, all of which are on Shineton Brook and vicinity, South Shropshire, England.
Lingulella nicholsoni.
- 304n** [McCoy, 1854, p. 254]. (For stratigraphic position and association, see p. 135.) Ordovician: "Coniston (Bala) limestone" at Coniston, Lancashire, England.
Lingulella davisi.
- 304o** [U. S. National Museum]. (For stratigraphic position and association, see p. 136.) Lower Cambrian: Sandstone at Nuneaton, England.
Micromitra (Paterina) labradorica.
- 304p** [Geol. Survey Great Britain]. (See 304l.) (For stratigraphic position and association, see p. 135.) Upper Cambrian: Shineton shales at the following localities of the Geological Survey of Great Britain: 2495, 2536, 2543, 2545, 2558, and 2580, all of which are on Shineton Brook, South Shropshire, England (Chas. Lapworth).
Acrotreta sabrinæ.
- 305** [Davidson, 1871, p. 341]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Tremadoc shales, Craig-y-dinas, North Wales.
**Acrotreta belti*.
- 305a** [Davidson, 1866, desc. of Pl. III]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper Tremadoc beds at Moel-y-gest, northwest side, Carnarvonshire, North Wales.
Lingulella lepis.
- 305c.** (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Tremadoc slate, everywhere in the Tremadoc district, Carnarvonshire, North Wales.
Lingulella lepis.
- 305d** [Davidson, 1866, p. 54]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: In the Upper *Lingula* flags near Tremadoc, Carnarvonshire, North Wales.
Lingulella lepis?
- 305e** [Davidson, 1866, p. 54]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper Tremadoc beds near Tai-hirion, Arenig, North Wales.
Lingulella lepis.
- 305f** [Davidson, 1866, p. 54]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Tremadoc beds east of Pont Nant-y-Ladron, on the Bala road from Ffestiniog, Merionethshire, North Wales.
Lingulella lepis.
- 305g** [Davidson, 1866, p. 54]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Tremadoc at Wern, North Wales.
Lingulella lepis.
- 305h** [Davidson, 1866, p. 54]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Tremadoc at Borthwood, North Wales.
**Lingulella lepis*.
- 305i** [Davidson, 1866, p. 54]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Tremadoc at Trwyn-y-Iago, North Wales.
Lingulella lepis.
- 305j** [Davidson, 1866, p. 54]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower Tremadoc at Cefn Cyfarnedd, North Wales.
Lingulella lepis.
- 306** [Geol. Survey Canada]. Upper? Cambrian: Sandy limestone on Gravel River, eastern slope of the Rocky Mountains, in the Mackenzie basin, British Columbia (J. Keele, 1908).
Billingsella coloradoensis.
Eoorthis desmopleura?

- 307** (references follow species). (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales of Division C3c of Matthew on McLeod Brook (=Barachois River), Cape Breton, Nova Scotia.
- Obolus refulgens* [Matthew, 1903, p. 213].
 **Lingulella concinna* [Matthew, 1903, p. 204].
Leptobolus gemmulus [Matthew, 1903, p. 192]=*Lingulella ferruginea*.
Leptobolus cf. linguloides [Matthew, 1903, p. 193]=*Lingulella ferruginea*.
Linnarssonina cf. belti [Matthew, 1903, p. 210].

- 312** [U. S. National Museum]. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Sandstones of 3d of the Waucoba Springs section [Walcott, 1908f, p. 187], east of Saline Valley road, east of Waucoba Springs, Inyo County, Cal.
Trematobolus excelsis.
Cruziana.
Holmia rowei.
- 312a** [U. S. National Museum]. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Sandstones of 3b of the Waucoba Springs section [Walcott, 1908f, p. 187], east of the Saline Valley road, east of Waucoba Springs, Inyo County, Cal.
Obolella vermilionensis.
Trematobolus excelsis.
- 313** [U. S. National Museum]. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone 0.75 mile (1.2 km.) east-northeast of McGill post office, White Pine County, Nev.
Micromitra (Paterina) crenistria. | Lingulella isse.
Lingulella desiderata. | Acrotreta idahoensis.
- 313a** [U. S. National Museum]. (Compare 313d and 313f.) (For stratigraphic position and association, see p. 140.) Middle Cambrian: Limestone at Schellbourne, Schell Creek Range, White Pine County, Nev.
Lingulella arguta?.
- 313b** [U. S. National Museum]. (For stratigraphic position and association, see p. 139.) Middle Cambrian: Limestone 3 miles (4.8 km.) north-northeast of Schellbourne, Schell Creek Range, White Pine County, Nev.
Micromitra (Paterina) crenistria.
Lingulella desiderata.
Acrotreta idahoensis alta.
- 313c** [U. S. National Museum]. (For stratigraphic position and association, see p. 139.) Middle? Cambrian: Limestone 12 miles (19.3 km.) west-southwest of Alpha Station, Eureka County, Nev.
Lingulella acutangula.
Lingulella desiderata.

- 313d** [U. S. National Museum]. (Compare 313a and 313f.) (For stratigraphic position and association, see p. 139.) Lower Ordovician: Limestone at Schellbourne, Schell Creek Range, White Pine County, Nev.
**Obolus rotundatus*.
- 313e** [U. S. National Museum]. (For stratigraphic position and association, see p. 139.) Middle Cambrian: Limestone 2 miles (3.2 km.) west of Green's ranch, White Pine County, Nev. (O. H. Hershey).
Lingulella arguta.
Linnarssonella girtyi.
- 313f** [U. S. National Museum]. (Compare 313a and 313d.) (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone at Schellbourne, Schell Creek Range, White Pine County, Nev.
**Lingulella arguta*.
**Lingulella manticula*.
**Acrotreta pyxidicula*. } These species are probably from more than one horizon.
- 313g** [U. S. National Museum]. (For stratigraphic position and association, see p. 158.) Lower Cambrian: Limestone at the southern end of the Timpahute Range, Groome district, near the line between Nye and Lincoln counties, Nev.
**Nisusia* (*Jamesella*) *erecta*.
Billingsella sp.
Callavia nevadensis Walcott. | *Olenellus fremonti* Walcott.
| *Peachella iddingsi* (Walcott).
- 313h** [U. S. National Museum]. (For stratigraphic position and association, see p. 139.) Upper Cambrian: Sandy shale on Hamburg Ridge, Eureka district [Hague, 1892, Atlas], Eureka County, Nev.
**Linnarssonella minuta*.
- 313i** [U. S. National Museum]. (For stratigraphic position and association, see p. 138.) Lower Cambrian: Limestone collected at long. 117° 20' W., lat. 38° N., in the western part of Esmeralda County, Nev.
Kutorgina perugata.
- 313j** [Hall and Whitfield, 1877, pp. 205 and 206]. (Specimens in U. S. National Museum.) (For stratigraphic position and association, see p. 139.) Upper Cambrian: Limestone in the Eureka district [Hague, 1892, Atlas], Eureka County, Nev.
**Obolus discoideus*.
**Obolus mæra*.
These species, in all probability, did not occur together; Hall and Whitfield give no further data, however, concerning their occurrence.
- 313k** [U. S. National Museum]. (See 214a and 214b.) (For stratigraphic position and association, see p. 139.) Ordovician: Limestone in the White Pine district, White Pine (?) County, Nev.
Linnarssonella minuta.
- 314** (references follow species). (For stratigraphic position and association, see p. 140.) Middle Cambrian: Limestone in *Paradoxides* zone, Chapple Arm, Trinity Bay, Newfoundland.
**Acrotreta misera* [Billings, 1872b, p. 470]. | **Anapolenus venustus* [Billings, 1872b, p. 474].
**Agraulos socialis* [Billings, 1872b, p. 472]. | **Paradoxides tenellus* [Billings, 1872b, p. 476].
**Solenopleura communis* [Billings, 1872b, p. 474]. | **Paradoxides decorus* [Billings, 1872b, p. 476].
- 314a** [Whiteaves, 1878, p. 226]. (For stratigraphic position and association, see p. 140.) Upper Cambrian: Shales on Kelleys Island, Conception Bay, Newfoundland.
**Lingulella billingsiana*.
- 314b** [Matthew, 1899e, p. 97]. (For stratigraphic position and association, see p. 141.) Lower Cambrian: Upper limestone of Matthew's Etcheminian at Smith Sound, Trinity Bay, Newfoundland.
**Kutorgina granulata*.
- 314c** [Billings, 1865a, p. 220]. (For stratigraphic position and association, see p. 140.) Lower Ordovician: Nodules of white limestone belonging to Division P of Billings's section at Cow Head, Newfoundland.
Syntrophia calcifera.
Bathyurus saffordi.

314d [Billings, Paleozoic fossils, vol. I]. (For stratigraphic position and association, see p. 140.) Lower Ordovician: Limestone of Division P of the "Quebec group" 4 miles (6.4 km.) northeast of Portland Creek, Newfoundland.

314e (references follow species). (For stratigraphic position and association, see p. 141.) Lower Cambrian: Limestone at Topsail Head, Conception Bay, Newfoundland.

Micromitra (*Paterina*) *bella* [Billings, 1872b, p. 478].

Scenella reticulata [Billings, 1872b, p. 479].

Agraulos strenuus [Billings, 1872b, p. 473.]

Walcott [1886a, p. 150] adds the following species:

| | |
|-----------------------------------------------------------|-------------------------------------|
| <i>Salterella</i> . | <i>Stenotheca rugosa</i> (Hall). |
| <i>Micromitra</i> (<i>Paterina</i>) <i>labradorica?</i> | <i>Protypus senectus parvulus</i> . |

314f [U. S. National Museum]. (For stratigraphic position and association, see p. 141.) Lower Cambrian: Limestone of B7 of the section at Bonne Bay [Walcott, 1891b, p. 255], Newfoundland.

Obolella chromatica.

Micromitra (*Paterina*) *labradorica*.

Mesonacis vermontana (Hall).

314g [Billings, 1865b, p. 362]. (For stratigraphic position and association, see p. 140.) Lower Ordovician: A loose piece of gray argillaceous limestone at Maiden Arm, Hare Bay, on the east side of the northern point of Newfoundland.

**Obolus? murrayi*.

314h [U. S. National Museum]. (For stratigraphic position and association, see p. 140.) Middle Cambrian: Shale on Manuels Brook, Conception Bay, Newfoundland.

Acrotreta misera.

314i [U. S. National Museum]. (For stratigraphic position and association, see p. 140.) Upper Cambrian: Shale picked up on beach in Smith Sound, Trinity Bay, Newfoundland (C. D. Walcott, 1899).

Orusia lenticularis.

315 (references follow species). Middle? Cambrian: Limestone at Curramulka, Yorke Peninsula, South Australia.

**Micromitra* (*Paterina*) *etheridgei* [Tate, 1892, p. 184].

Kutorgina peculiaris [Tate, 1892, p. 185].

**Nisusia compta* [Tate, 1892, p. 185].

315a [Tate, 1892, p. 185]. Middle? Cambrian: Limestone at Parara, near Ardrossan, Yorke Peninsula, South Australia.

**Kutorgina peculiaris*.

315b [Etheridge, 1905a, p. 249]. Middle? Cambrian: Limestone at Wirrialpa, Flinders Range, South Australia.

**Eoorthis tatei*.

315c [Etheridge, 1905, p. 250]. Middle? Cambrian: "Archæocyathinæ white limestone" at Wirrialpa, Flinders Range, South Australia.

**Huenella etheridgei*.

315d [Etheridge, 1905, p. 248, and U. S. National Museum]. Lower? Cambrian: Limestone near Wirrialpa, Flinders Range, South Australia.

**Obolella wirrialpensis*.

316 [Davidson, 1871, p. 343]. (For stratigraphic position and association, see p. 135.) Lower Ordovician: Upper Llandeilo (?) black shales at Dobbs Linn, near Moffat, in Dumfriesshire, Scotland.

**Acrotreta nicholsoni*.

316a [Davidson, 1883, p. 213]. (For stratigraphic position and association, see p. 135.) Lower Ordovician: Llandeilo at Craighead, Ardmillan Brae, and Balclatchie, all three in the Girvan district of Ayrshire, Scotland.
Acrotreta nicholsoni.

316b [Davidson, 1883, p. 211]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: At Cairn Burn and Druidhill Burn, both in Dumfriesshire, Scotland.
Acrotreta sagittalis.

316c [Geol. Survey Scotland, M4197d; personal communication, J. Horne, 1910]. (For stratigraphic position and association, see p. 136.) Lower Cambrian: Probably equivalent to those in band 6 or 7 of the section on the north slope of Meall á Ghiubhais [Peach and Horne, 1907, p. 414], on the Bruachaig River, 2 miles (3.2 km.) east-northeast of the Kinlochewe Hotel, Loch Maree, Ross-shire, Scotland.

**Lingulella zeus*.

Olenellus lapworthi? Peach and Horne.

316d [Geol. Survey Scotland, M2646e, M2647e, and M4178d; personal communication, J. Horne, 1910]. (For stratigraphic position and association, see p. 136.) Lower Cambrian: About 500 feet (152.5 m.) above the provisional base of the Cambrian and 75 feet (23 m.) below what is believed to be the top of the Lower Cambrian, in the shales forming 5 and 6 of the section given by Peach and Horne [1907, p. 414], in a small burn on the north slope of Meall á Ghiubhais, 4 miles (6.4 km.) west-northwest of the Kinlochewe Hotel, Loch Maree, Ross-shire, Scotland.

**Micromitra scotica*.

Olenellus lapworthi? Peach and Horne.

317 [Davidson, 1883, p. 213]. Lower Ordovician: Coalpit Bay, County Down, Ireland.
Acrotreta nicholsoni.

317a [Davidson, 1871, p. 340]. Middle Cambrian: At Bellewstown, County Meath, and at Balbriggan, County Dublin, both in Ireland.
Acrotreta sagittalis?

317b [Davidson, 1866, p. 58]. Middle Cambrian: Shales at Bellewstown, County Meath, Ireland.
Lingulella dayisi.

318 [Davidson, 1869, p. 232]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags at Penmain Pool, west of Dolgelly, Merionethshire, North Wales.
Orusia lenticularis.

318a [Davidson, 1868, p. 314]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags at Criccieth, Carnarvonshire, North Wales.
Orusia lenticularis.

318b [Davidson, 1869, p. 232]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags near Portmadoc, Carnarvonshire, North Wales.
Orusia lenticularis.

318c [Davidson, 1868, p. 310]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at the Rheider Waterfall Valley and at Gwynfynydd and other places near Dolgelly, North Wales.
Acrotreta sagittalis.

318d (references follow species). (For stratigraphic position and association, see p. 136.) Middle Cambrian: Sandstones in the middle portion of the Menevian at Porth-y-rhaw, St. Davids, South Wales.
Acrothele maculata [Davidson, 1871, p. 341].

**Orbiculoidea pileolus* [Davidson, 1868, p. 316].

**Billingsella hicksi* [Davidson, 1869, p. 230].

318e (references follow species). (For stratigraphic position and association, see p. 136.) Middle Cambrian: Lower portion of the Menevian at Camlan, North Wales.

Lingulella ferruginea [Davidson, 1871, p. 337].

Acrothele maculata [Davidson, 1871, p. 341].

Orbiculoidea pileolus [Davidson, 1871, p. 345].

318f [Davidson, 1871, p. 341]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Lower portion of the Menevian at Gwynfynydd, North Wales.
Acrothele maculata.

318g [Davidson, 1868, p. 310]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Porth-y-rhaw, Pen-y-pleidiau, and several other localities near St. Davids, South Wales.
**Acrotreta sagittalis*.

- 318h** [U. S. National Museum]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Shales in the Menevian at St. Davids, South Wales.
Lingulella ferruginea. | *Acrotreta sagittalis*.
Acrothele maculata. | *Billingsella hicksi*.
- 318i** [U. S. National Museum]. (See 366c.) (For stratigraphic position and association, see p. 136.) Middle? Cambrian: Red shales of the Caerfai group at St. Davids, South Wales.
Lingulella primæva.
- 318j** [Salter, 1866b, p. 340]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Black sbales of the Menevian group at Pen-y-pleidiau, St. Davids, South Wales.
 **Lingulella ferruginea*.
- 318k** [Davidson, 1871, p. 337]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: In the Menevian rocks at Tafern Helig, North Wales.
Lingulella ferruginea.
- 318l** [Davidson, 1871, p. 337]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: In the Menevian rocks at the Waterfall Valley, near Maentwrog, North Wales.
Lingulella ferruginea.
- 318m** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Near the base of the lower black slates at the Waterfall Valley, near Maentwrog, North Wales.
Lingulella davisii.
- 318n** [Davidson, 1871, p. 337]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Red shales at the base of the Harlech grits at St. Davids, South Wales.
Lingulella ferruginea.
- 318o** [Davidson, 1871, p. 337]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Red shales at the base of the Harlech grits at Solva, St. Davids, South Wales.
Lingulella ferruginea.
- 318p** (references follow species). (For stratigraphic position and association, see p. 136.) Middle Cambrian: Sandstones in the middle portion of the Menevian at Ninewells, near St. Davids, South Wales.
Orbiculoidea pileolus [Davidson, 1871, p. 344].
 **Billingsella hicksi* [U. S. National Museum and Davidson, 1869, p. 230].
- 318q** [Davidson, 1871, pp. 344-345]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Yellowish-gray beds in the Harlech group, on the road between Solva and Whitechurch, St. Davids, South Wales.
Orbiculoidea pileolus?
- 318r** [Davidson, 1871, p. 344]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Sandstones in the middle portion of the Menevian at Solva Harbor, St. Davids, South Wales.
Orbiculoidea pileolus.
- 318s** [Davidson, 1868, p. 314]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags at Ogof-ddu Cliff, Carnarvonshire, North Wales.
Orusia lenticularis.
- 318t** [Davidson, 1868, p. 314]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags at Penmorfa Church, Tremadoc, Carnarvonshire, North Wales.
Orusia lenticularis.
- 318u** (references follow species). (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags at Gwern-y-Barcud, North Wales.
Lingulella ferruginea [Davidson, 1868, p. 315].
Orusia lenticularis [Davidson, 1868, p. 314].
- 318v** (references follow species). (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags at Rhiwfelyn, North Wales.
Lingulella ferruginea [Davidson, 1868, p. 315].
Orusia lenticularis [Davidson, 1869, p. 232].
- 318w** [U. S. National Museum]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Tremadoc shale on Ramsey Island, St. Davids, South Wales.
Eoorthis carausii.

319 [Geol. Survey Canada]. (See 319i; may be same locality.) Lower Ordovician: Limestone No. 1 of Billings's Point Levis section, Point Levis, Province of Quebec, Canada.

*Elkania ida.

*Acrotreta ovalis.

The following species are quoted from this locality by Billings, *Paleozoic Fossils*, vol. 1:

Metoptoma venillia (p. 88).

*Orthis ? apicalis (p. 301).

*Agnostus canadensis (p. 397).

*Agnostus orion (p. 397).

*Conocephalites zenkeri (p. 398).

*Arionellus cylindricus (p. 406).

*Arionellus subclavatus (p. 406).

*Menocephalus globosus (p. 408).

*Menocephalus sedgwicki (p. 407).

*Dikellocephalus belli (p. 403).

*Dikellocephalus cristatus (p. 404).

*Dikellocephalus hisingeri (p. 196).

*Dikellocephalus magnificus (p. 399).

*Dikellocephalus megalops (p. 403).

*Dikellocephalus oweni (p. 402).

*Dikellocephalus panper (p. 200).

*Dikellocephalus planifrons (p. 401).

*Dikellocephalus selectus (p. 199).

*Dikellocephalus sesostris (p. 198).

*Bathyurus armatus (p. 411).

*Bathyurus capax (p. 409).

*Bathyurus dubius (p. 410).

319a (references follow species). Lower Ordovician: Levis shales, Point Levis, Province of Quebec, Canada.

*Lingulella irene [Billings, 1862b, p. 72].

*Acrothele levisensis (Geol. Survey Canada).

*Elkania desiderata [U. S. National Museum and Billings, 1862b, p. 70].

Lingulella sp. undt. (U. S. National Museum).

319b [U. S. National Museum]. Lower Cambrian: Conglomeratic limestones containing *Olenellus?*, St. Simon, Rimouski (?) County, Province of Quebec, Canada.

Bicia gemma.

Obolella crassa.

*Obolella crassa elongata.

*Acrothele sp. nndt. a.

Hyolithes americanus Billings.

Olenellus?.

Agraulos redpathi Walcott.

Billingsella salemensis occurs at the same locality as the specimens mentioned above, but its stratigraphic position is not known.

319c [Billings, 1862b, p. 69]. Ordovician: Shales at Cape Rouge, above Quebec, Province of Quebec, Canada. *Acrothele pretiosa*.

319d [Billings, 1865a, p. 301]. Upper Cambrian: Limestone boulder in Lower Ordovician conglomerate, Point Levis, Quebec, Canada.

*Lingulella iris.

319e (references follow species). Lower Cambrian: Sandy shales about 2 miles (3.2 km.) east of Swanton, Franklin County, Vt. (See Locality 25a; the only known locality is nearly 2 miles east of Swanton, and Locality 319e has therefore been entered as 2 miles, though Billings gives it as 1.5 miles.)

Kntorgina cingulata [Billings, 1861b, p. 9].

**Nisusia festinata* [Billings, 1861b, p. 10].

**Swantonina antiquata* [U. S. National Museum and Billings, 1861b, p. 11].

319f [U. S. National Museum]. Lower Ordovician: Drift boulder of sandstone found near St. Albans, Franklin County, Vt. The lithologic characters of the matrix in which this species was found point to the arenaceous limestones of the Phillipsburg formation just north of the boundary between the United States and Canada as the source of the boulder.

**Billingsella dice*.

319g [Whitfield, 1884, p. 144]. Lower Cambrian: Shales at Parker's quarry, near Georgia, Franklin County, Vt.

**Billingsella orientalis*.

Olenellus thompsoni.

319h [U. S. National Museum]. Lower Cambrian: Limestone boulders in conglomerate at Metis, on the St. Lawrence, below Quebec, Canada.

Billingsella salemensis.

Hyolithellus micans (Billings).

Olenellus? sp.

Ptychoparia metisensis Walcott.

319i [Billings, 1862b, p. 71, and Geol. Survey Canada]. (See 319; may be same locality.) Lower Ordovician: Limestone at Point Levis, Province of Quebec, Canada.

Elkania ida.

319j [U. S. National Museum]. (See 319k.) Lower Cambrian: Sandstone 50 feet (15 m.) above the base of the section west of Parker's quarry and about a mile (1.6 km.) from the shore of Lake Champlain, in the township of Georgia, Franklin County, Vt.

Botsfordia cæolata.

Hyolithellus micans (Billings).

Hyolithes americanus Billings.

Hyolithes communis Billings.

Hyolithes sp.

Olenellus? sp.

Ptychoparia trilineata (Emmons).

319k [U. S. National Museum records]. (See 319j.) Lower Cambrian: Calcareous sandstone near the base of the section west of Parker's quarry, on cliff overlooking Lake Champlain, near Georgia, Franklin County, Vt.
Obolella crassa.

319l [Billings, 1872a, p. 220, and U. S. National Museum.] Lower Cambrian: Limestone boulders in conglomerate at Trois Pistoles, Temiscouata County, on St. Lawrence River, below Quebec, Canada.

**Quebecia circe*.

319m [Walcott, 1891b, p. 278]. Lower Cambrian: Shales of No. 6 of the section at Parker's quarry, near Georgia, Franklin County, Vt.

Kutorgina cingulata.

Billingsella orientalis.

Nisusia festinata.

Nisusia festinata transversa.

**Palæophycus congregatus* Billings.

**Palæophycus incipiens* Billings.

Phyllograptus (?) *cambrensis* Walcott.

**Climacograptus* (?) *emmonsi* Walcott.

**Microdiscus parkeri*.

**Mesonacis vermontana* (Hall).

**Olenellus thompsoni* (Hall).

**Olenoides marconi* (Whitfield).

**Bathynotus holopyga* (Hall).

Ptychoparia adamsi (Billings).

Ptychoparia vulcanus (Billings).

**Protypus hitchcocki* (Whitfield).

Protypus senectus (Billings).

Protypus senectus parvulus (Billings).

319n [Billings, 1859, p. 432]. Ordovician: "Chazy formation" on the island of Montreal, in St. Lawrence River, Canada.

**Obolus belli*.

319o [Billings, 1859, p. 432]. Ordovician: "Chazy formation" near L'Original, on St. Lawrence River, Canada.
Obolus belli.

319p [Billings, 1859, p. 432]. Ordovician: "Chazy formation" on Allumette Island, in St. Lawrence River, Canada.
Obolus belli.

319q [U. S. National Museum records]. Upper Cambrian: Limestone 1 mile (1.6 km.) south-southwest of Highgate Falls, Franklin County, Vt.
Obolus mæra?.

319r [U. S. National Museum]. (See 319e and 25a.) Lower Cambrian: On the Bullard farm, about 2 miles (3.2 km.) east of Swanton, Franklin County, Vt.

Rustella edsoni.

Olenellus thompsoni (Hall).

319s [U. S. National Museum]. Middle Cambrian: "St. Albans formation" at St. Albans, Franklin County, Vt.
Obolus matinalis?.

**Huenella vermontana*.

Paradoxides sp.

319t [Billings, 1865a, p. 220]. Lower Ordovician: "Calciferos sandrock" at St. Timothy, on the St. Lawrence, near the head of the Beauharnois Canal, Province of Quebec, Canada.

Syntrophia calcifera.

319u [Billings, 1861a, p. 320]. Lower Ordovician: "Calciferos sandrock" in the township of Edwardstown, between Beauharnois and Lake Champlain, Province of Quebec, Canada.

Syntrophia calcifera.

319v [U. S. National Museum]. (See 319y.) Lower Cambrian: Sandy shale 2 miles (3.2 km.) east of Highgate Springs, Franklin County, Vt. (C. D. Walcott, 1889).

Lingulella franklinensis.

319w [U. S. National Museum]. (See 319x.) Lower Cambrian: Limestone 1.25 miles (2 km.) north of Rutland, Rutland County, Vt. (T. N. Dale).

Nisusia festinata.

- 319x** [U. S. National Museum]. (See 319w.) Lower Cambrian: Limestone at the crossing of East Creek and Grove Street, 1.25 miles (2 km.) north of Rutland, Rutland County, Vt. (A. F. Foerste, 1890).
Micromitra (*Paterina*) *labradorica swantonensis*.
- 319y** [U. S. National Museum]. (See 26 and 319v.) Lower Cambrian: Sandstone 2 miles (3.2 km.) east-southeast of Highgate Springs, Franklin County, Vt. (C. D. Walcott, 1889).
Micromitra (*Paterina*) *labradorica swantonensis*.
Stenotheca rugosa (Hall).
Ptychoparia sp.
- 319z** [U. S. National Museum]. (See 25a.) Lower Cambrian: Sandy limestone 2.5 miles (4 km.) east of Swanton, Franklin County, Vt. (C. D. Walcott, 1897).
Micromitra (*Paterina*) *labradorica swantonensis*.

- 336u** [Eichwald, 1860, p. 925]. (For stratigraphic position and association, see p. 143.) Upper Cambrian: *Obolus* sandstone on the bank of Louga (Luga) River, southwest of St. Petersburg, Russia.
Obolus apollinis.
- 336v** [Gagel, 1890, desc. of Pl. I]. (For stratigraphic position and association, see p. 143.) Ordovician: *Echinospærites* limestone at Reval, Government of Esthonia, Russia.
Siphonotreta unguiculata.
- 336w** (references follow species). (For stratigraphic position and association, see p. 143.) Ordovician: Near Pawlowsk, near St. Petersburg, Russia.
Siphonotreta unguiculata [Eichwald, 1840, p. 140 (26)].
Siphonotreta verrucosa [Eichwald, 1840, p. 141 (27)].
- 336x** [de Verneuil, 1845, p. 287]. (For stratigraphic position and association, see p. 143.) Ordovician: In the Archangel quarry, on Volkhof (Wolchow) River, east of St. Petersburg, Russia.
Siphonotreta unguiculata.
- 336y** [U. S. National Museum]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: Glauconite limestone at Popowka, near St. Petersburg, Russia.
Siphonotreta unguiculata.
Siphonotreta verrucosa.
- 336z** [Schmidt, 1861, pp. 218 and 248]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone ("Vaginatenkalk") at Narwa, Government of Esthonia, Russia.
Siphonotreta unguiculata.
- 337** [Schmidt, 1861, pp. 218 and 248]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone ("Vaginatenkalk") at Erras, 85 miles (137 km.) east of Reval, Government of Esthonia, Russia.
Siphonotreta unguiculata.
- 337a** [Schmidt, 1861, pp. 218 and 248]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone ("Vaginatenkalk") at Kusal, 25 miles (40 km.) east of Reval, Government of Esthonia, Russia.
Siphonotreta unguiculata.
- 337b** [Schmidt, 1861, pp. 218 and 248]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone ("Vaginatenkalk") at Reval, Government of Esthonia, Russia.
 **Siphonotreta unguiculata*.^a
- 337c** [Schmidt, 1861, pp. 218 and 248]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone ("Vaginatenkalk") on Odensholm Island, 55 miles (88.6 km.) west of Reval, Government of Esthonia, Russia.
Siphonotreta unguiculata.

^a May be the type locality. Eichwald [1829, p. 274] gives it as "limestone at Reval."

- 337d** [Schmidt, 1861, p. 218]. (For stratigraphic position and association, see p. 143.) Ordovician: "Brandschiefer" at Salla, near Erras, 85 miles (137 km.) east of Reval, Government of Esthonia, Russia.
Siphonotreta unguiculata.
- 337e** [Schmidt, 1861, p. 218]. (For stratigraphic position and association, see p. 143.) Ordovician: "Jewesche Schicht" at Altenhof, near Pöddrus, 55 miles (88.6 km.) east of Reval, Government of Esthonia, Russia.
Siphonotreta unguiculata.
- 337f** [Schmidt, 1861, pp. 218 and 248]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone ("Vaginatenkalk") at Türsel, 15 miles (24.2 km.) west of Narwa, Government of Esthonia, Russia.
Siphonotreta verrucosa.
- 337g** [Schmidt, 1861, pp. 218 and 248]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone ("Vaginatenkalk") at Chudleigh, 25 miles (40 km.) west of Narwa, Government of Esthonia, Russia.
Siphonotreta verrucosa.
- 337h** [Eichwald, 1860, p. 929]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone near Reval, Government of Esthonia, Russia.
Obolus (*Acritis*) antiquissimus.
- 337i** [Schmidt, 1861, p. 218]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: "Green sand" at Baltischport, Government of Esthonia, Russia.
Obolus (*Mickwitzella*) siluricus.
- 337j** [Fr. Schmidt, personal communication, 1908]. (For stratigraphic position and association, see p. 143.) Ordovician: Zone BIII α or BIII β , characterized by *Asaphus raniceps*, a little above the zone with *Asaphus expansus*, in the *Orthoceratite* limestone at Obookhov (Obuchow), on Volkhof (Wolchow) River, Government of St. Petersburg, Russia.
Volborthia recurva.
- 337k** [Eichwald, 1860, p. 916]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone on the banks of Volkhof (Wolchow) River, near Lake Ladoga, near St. Petersburg, Russia.
Siphonotreta unguiculata.
- 337l** [Eichwald, 1860, p. 916]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone at Baltischport, west of Reval, Government of Esthonia, Russia.
Siphonotreta unguiculata.
- 337m** [Eichwald, 1860, p. 916, and U. S. National Museum]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: *Orthoceratite* limestone at Popowka, near St. Petersburg, Russia.
Siphonotreta unguiculata.
Siphonotreta verrucosa.
- 338** [U. S. National Museum]. (See 29a.) Lower Cambrian: Limestone at Schodack, northeastern corner of Cox-sackie quadrangle (U. S. G. S.), Rensselaer County, N. Y.
Acrotreta sagittalis taconica.
- 338a** [U. S. National Museum]. Lower Cambrian: Limestone in the northeast section of Whitehall township, Whitehall quadrangle (U. S. G. S.), Washington County, N. Y.
Acrotreta sagittalis taconica.
- 338b** [U. S. National Museum]. (See 29.) Lower Cambrian: Limestone on Kinderhook Creek, near Stockport paper mill, Kinderhook quadrangle (U. S. G. S.), Columbia County, N. Y.
Acrotreta sagittalis taconica.
- 338c** [U. S. National Museum]. (See 33.) Lower Cambrian: Limestone at Rock Hill schoolhouse, near North Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y.
Acrotreta sagittalis taconica.
- 338d** [U. S. National Museum]. (See 36; may be same locality.) Lower Cambrian: Limestone 1 mile (1.6 km.) south of Shushan, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y.
Acrotreta sagittalis taconica.
Billingsella salemensis. } These species may not occur in the same bed.
- 338e** [U. S. National Museum]. Lower Cambrian: Limestone a little west of North Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y.
Acrotreta sagittalis taconica.

- 338f** [U. S. National Museum]. Lower Cambrian: Limestone near Argyle, 8 miles (12.8 km.) north of Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y.
Acrotreta sagittalis taconica.
- 338g** [U. S. National Museum]. Lower Cambrian: Limestone in the town of Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y.
Acrotreta sagittalis taconica.
- 338h** [U. S. National Museum]. (See Walcott, 1888, pp. 316 and 317, for section.) Lower Cambrian: Limestone on the summit of Bald Mountain, about 2 miles (3.2 km.) northwest of Greenwich, Schuylerville quadrangle (U. S. G. S.), Washington County, N. Y.
Botsfordia cælata.
Acrotreta sagittalis taconica.
Obolella sp. | Hyolithellus micans (Billings).
| Microdiscus speciosus Ford.
| Olenellus thompsoni (Hall).
- 338i** [U. S. National Museum]. Ordovician: Shales 1 mile (1.6 km.) west-northwest of South Argyle, near the line between the Schuylerville and Cambridge quadrangles (U. S. G. S.), Washington County, N. Y.
Acrothele pretiosa.
- 338j** [Hall, 1847, p. 4]. Upper Cambrian: Potsdam sandstone near Alexandria Landing, Jefferson County, N. Y.
Lingulella (Lingulepis) acuminata.
- 338k** [U. S. National Museum]. (See 72a.) Lower Cambrian: Limestone 2.5 miles (4 km.) southwest of Wynantskill, Rensselaer County, N. Y. (L. M. Prindle, 1893).
Obolus prindlei.
- 338l** [U. S. National Museum]. (See 39a.) Lower Cambrian: Limestone in the northern part of Easton, 3 miles (4.8 km.) south of Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y.
Lingulella granvillensis.
- 338m** [U. S. National Museum]. Lower Cambrian: Limestone on the roadside north of schoolhouse No. 4, in the northeast part of Whitehall, Whitehall quadrangle (U. S. G. S.), Washington County, N. Y.
Lingulella granvillensis.
- 338n** [U. S. National Museum]. Lower Cambrian: Western belt of conglomeratic limestone, Rensselaer County, N. Y.
Yorkia washingtonensis.
Microdiscus lobatus (Hall).
- 338o** [?]. Lower Cambrian: Shale on Moses Hill, 2 miles (3.2 km.) west of North Greenwich, near the line between the Schuylerville and Cambridge quadrangles (U. S. G. S.), Washington County, N. Y.
Obolella crassa.
- 338p** [U. S. National Museum]. Lower Cambrian: Sandy limestone 0.25 mile (0.4 km.) northwest of schoolhouse No. 7, in Greenwich, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y.
Obolella chromatica.
- 338q** [Hall, 1847, p. 290]. Lower Cambrian: Calcareous beds 2 miles (3.2 km.) northeast of Troy, Troy quadrangle (U. S. G. S.), Rensselaer County, N. Y.
*Obolella crassa.
- 338r** [Billings, 1856, p. 34]. Upper Cambrian: Potsdam sandstone at Keeseville, Essex County, N. Y.
Lingulella (Lingulepis) acuminata.
- 338s** [Emmons, 1842, pp. 267 and 268]. Upper Cambrian: Potsdam sandstone at High Bridge, on Ausable River, Essex County, N. Y.
*Lingulella (Lingulepis) acuminata.
- 338t** [U. S. National Museum records]. Upper Cambrian: Potsdam sandstone in Ausable Chasm, below Keeseville, Essex County, N. Y.
Lingulella prima.
Lingulella (Lingulepis) acuminata.
- 338u** [U. S. National Museum records]. Ordovician and Upper Cambrian: In the strata from the upper layers of the Potsdam sandstone to the lower portion of the "Calcareous sand rock" at Chateaugay Falls, Franklin County, N. Y.
Lingulella (Lingulepis) acuminata (associated with Ophileta complanata in the upper beds).
- 338v** [U. S. National Museum]. Ordovician: Shale 1 mile (1.6 km.) southwest of Middle Granville, Mettawee quadrangle (U. S. G. S.), Washington County, N. Y.
*Obolus sp. undt. a.

- 338w** [Hall, 1847, p. 4]. Upper Cambrian: Potsdam sandstone at Hammond, St. Lawrence County, N. Y.
Lingulella (*Lingulepis*) acuminata.
- 338x** [U. S. National Museum]. Lower Cambrian: Limestone 0.5 mile (0.8 km.) south of Coila, just east of Cambridge, Cambridge quadrangle (U. S. G. S.), Washington County, N. Y. (C. D. Walcott, 1886).
Lingulella sp.
Acrotreta sagittalis taconica.
- 338y** [U. S. National Museum]. Lower Cambrian: Limestone north of Eagle Mills, Rensselaer County, N. Y. (T. N. Dale).
Acrotreta sagittalis taconica.
- 338z** [U. S. National Museum]. Ordovician: Limestone on the north side of Bald Mountain, about 2 miles (3.2 km.) northwest of Greenwich, Schuylerville quadrangle (U. S. G. S.), Washington County, N. Y. (F. H. Moffit, 1902).
Acrothele pretiosa.
- 339** [Sardeson, 1896, pp. 95 and 96]. Lower Ordovician: Oneota dolomite, Stillwater, Washington County, Minn.
**Obolus dolatus*.
Orthis (*Billingsella*) *pepina*=*Billingsella coloradoensis*.
- 339a** [Sardeson, 1896, p. 95]. Upper Cambrian: St. Lawrence formation at Otisville, Washington County, Minn.
Obolus (*Westonia*) *aurora*.
- 339b** [U. S. National Museum]. Upper Cambrian: "St. Croix sandstone" at Arcola on St. Croix River, 7 miles (11.2 km.) above Stillwater, Washington County, Minn.
Lingulella winona.
- 339c** [U. S. National Museum]. Upper Cambrian: Reeds Landing, foot of Lake Pepin, Wabasha County, Minn.
Obolus (*Westonia*) *aurora*.
- 339d** [U. S. National Museum]. (See 82b; may be same locality.) Upper Cambrian: "St. Croix sandstone" at Taylors Falls, Chisago County, Minn.
Obolus matinalis.
Lingulella similis.
| *Eoorthis remnicha sulcata*.
| *Syntrophia primordialis*.
- 339e** [U. S. National Museum]. Middle Cambrian: "St. Croix sandstone" on Mountain Island, Minnesota, in Mississippi River, just above the mouth of Trempealeau River. (See p. 159.)
**Lingulella ampla*.
Dicellomus politus.
- 339f** [U. S. National Museum]. Upper Cambrian: "St. Croix sandstone" near Minneiska (Miniska), on Mississippi River, near the line between Wabasha and Winona counties, Minn. (F. M. Brown).
Obolus matinalis.
Billingsella coloradoensis.
Fiukelburgia finkelburgi.
- 339g** [U. S. National Museum]. Upper Cambrian: "St. Croix sandstone" just below the beds with *Dikellocephalus minnesotensis* near Winona, Winona County, Minn.
Billingsella coloradoensis.
Finkelburgia osceola.
| *Finkelburgia osceola corrugata*.
| *Syntrophia primordialis*.
- 339h** (references follow species). Upper Cambrian: "St. Croix sandstone" near the mouth of Minneiska (Miniska) River, near the line between Wabasha and Winona counties, Minn.
Obolus matinalis [Hall, 1863, p. 130].
Lingulella (*Lingulepis*) *acuminata* [Hall, 1863, p. 130].
Orthis pepina [Hall, 1863, p. 135]=*Billingsella coloradoensis*.
- 339i** [Owen, 1852, desc. of Pl. 1B]. Middle Cambrian: Sandstones of Flb of Owen's section, below Mountain Island, in Mississippi River, nearly opposite the old mouth of Black River, southeastern Minnesota. (See p. 159.)
**Dicellomus politus*.
- 339j** [U. S. National Museum]. Middle Cambrian: Sandstone between the lowest blue shale and the reddish calcareous beds above, at Taylors Falls, Chisago County, Minn. (Chas. Schuchert). (See p. 159.)
Lingulella (*Lingulepis*) *acuminata*.
- 339k** [U. S. National Museum]. Middle Cambrian: Sandstone near Winona, Winona County, Minn. (See p. 159.)
Lingulella (*Lingulepis*) *acuminata*.
- 340** [U. S. National Museum]. (See 5f.) Middle Cambrian: Limestone in Meagher County, on the road to Wolsey, about 1 mile (1.6 km.) below the divide and 13 miles (21 km.) south of Neihart, Little Belt Mountains quadrangle (U. S. G. S.), Cascade County, Mont. (W. H. Weed, F. B. Weeks, and C. D. Walcott, 1895).
Micromitra pealei.

- 340a** [U. S. National Museum]. (Same horizon as 4u.) Middle Cambrian: Shales near Helena, Jefferson County, Mont. (L. S. Griswold).
Obolus (*Westonia*) *ella*.
- 340b** [U. S. National Museum]. Upper Cambrian: Limestone at the mouth of Fourmile Creek, probably somewhere in the Threeforks quadrangle (U. S. G. S.), Gallatin County, Mont. (A. C. Peale).
Eoorthis desmopleura.
- 340c** [U. S. National Museum]. Middle? Cambrian: Dark-red sandstone near the base of the Cambrian at Rawlins, Carbon County, Wyo. (N. H. Darton).
Lingulella (*Lingulepis*) *acuminata*.
- 340d** [U. S. National Museum]. Middle Cambrian: Limestone near the head of Bear River Canyon, Wyo. (A. C. Peale).
Acrotreta attenuata.
- 340e** [U. S. National Museum]. Middle? Cambrian: Shale on the west side of Cable Mountain, Phillipsburg quadrangle (U. S. G. S.), Granite County, Mont. (F. C. Calkins, 1906).
Lingulella sp.
- 340f** [U. S. National Museum]. Middle? Cambrian: Lowest beds exposed at the mouth of Bear Creek, Little Belt Mountains, Mont. (W. H. Weed, 1894).
Dicellomus politus.
- 341** [U. S. National Museum]. Upper Cambrian: Near Lansing, Allamakee County, Iowa.
**Lingulella winona* (also cited from this locality by Hall, 1863, p. 126).
Finkelburgia osceola.
- 341a** [U. S. National Museum]. Upper Cambrian: Sandstone at McGregor, Clayton County, Iowa (F. W. Sardeson, 1899).
Lingulella mosia.
- 342** [collection of J. Miquel]. Middle Cambrian: Shales in Montagne Noire, Coulouma, Department of Hérault, France.
**Acrothele bergeroni*.
- 342a** [collection of J. Miquel]. Passage beds between the Cambrian and the Ordovician, or Lower Ordovician: Barren quartzitic beds, Coulouma, Department of Hérault, France.
**Yorkia?* *miqueli*.
- 343** [Rogers, 1875, p. 11, mentions specimens from Newport; U. S. National Museum has specimens labeled Narragansett Bay]. Lower Ordovician: Limestone pebbles on the beach near Newport and at several points along the shores of Narragansett Bay, Rhode Island.
**Obolus* (*Westonia*) *rogersi*.
- 343a** [U. S. National Museum]. Upper Cambrian: Limestone pebbles on Checker Beach, near Newport, R. I. (O. O. Nylander, 1893).
Lingulella sp. 1.
Lingulella sp. 2.
- 343b** [U. S. National Museum]. Upper Cambrian: Limestone pebble on Sachuset Beach, near Newport, R. I.
Lingulella bella.
- 344** (references follow species). (For stratigraphic position and association, see p. 133.) Middle Cambrian: Sandy shales of Division E3b of Matthew's [1903, p. 21] Etcheminian, on Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia.
Obolus lens [Matthew, 1903, p. 81]=*Obolus* (*Palæobolus*) *lens*.

Lingulella (Lingulepis) acuminata.
- 360h [U. S. National Museum]. (100 feet above 360i; see locality 3g.) Upper Cambrian: Sandy shales about 200 feet (61 m.) above the base of the section at Glenwood Springs, Garfield County, Colo. (T. W. Stanton, 1889).
Obolus mæra.
- 360i [U. S. National Museum]. (100 feet below 360h; see locality 3g.) Upper Cambrian: Sandstones about 100 feet (30 m.) above the base of the section at Glenwood Springs, Garfield County, Colo. (T. W. Stanton, 1889).
Obolus mæra.

- 361** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shaly limestone in suburb of Attalla, Etowah County, Ala. (M. R. Campbell).
Lingulella desiderata.
Acrotreta kutorgai.
- 362** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Upper Cambrian: Shales in the Oothkalooga Valley, Bartow County, Ga.
Lingulella desiderata.
- 362a** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandy shale a short distance west of Cave Spring, Floyd County, Ga.
Lingulella similis.
- 364** [Sardeson, 1896, p. 95]. Upper Cambrian: St. Lawrence formation in both Wisconsin and Minnesota.
Lingulella mosia.
- 364a** [Sardeson, 1896, p. 95]. Lower Ordovician: "Oneota dolomite" along St. Croix River in both Wisconsin and Minnesota.
Lingulella mosia.
- 366** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Whitesand Bay, near St. Davids Head, Pembrokeshire, South Wales.
Lingulella davisii.
- 366a** [U. S. National Museum]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper portion of Middle *Lingula* flags 6 miles (9.6 km.) east of Ffestiniog, Merionethshire, North Wales.
Lingulella davisii.
- 366b** [U. S. National Museum]. (For stratigraphic position and association, see p. 136.) Middle Cambrian: Red shales at the base of the Harlech grits at Porthclais Harbor, south of St. Davids, South Wales.
Lingulella ferruginea.
- 366c** [Salter and Etheridge, 1881, p. 538]. (See 318i.) (For stratigraphic position and association, see p. 136.) Middle? Cambrian: "Caerfai group" at Caerfai, Nuns Hill, and Porthclais Harbor, south of St. Davids, South Wales.
*Lingulella primæva.
- 366d** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Carnedd Filiast, Bangor, Carnarvonshire, North Wales.
Lingulella davisii.
- 366e** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Marchillyn-mawr, Llanberis, Carnarvonshire, North Wales.
Lingulella davisii.
- 366f** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Ffestiniog, Merionethshire, North Wales.
Lingulella davisii.
- 366g** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Dolgelly, Merionethshire, North Wales.
Lingulella davisii.
- 366h** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Pen-y-Bryn, 5 miles (8 km.) north of Dolgelly, Merionethshire, North Wales.
Lingulella davisii.
- 366i** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Llyn Dywarchen, Merionethshire, North Wales.
Lingulella davisii.
- 366j** [Davidson, 1866, p. 57.] (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Pont Nant-y-Lladron, on the Bala Road from Ffestiniog, Merionethshire, North Wales.
Lingulella davisii.
- 366k** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Penmorfa, Merionethshire, North Wales.
Lingulella davisii.
- 366l** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Tremadoc, Merionethshire, North Wales.
Lingulella davisii.

- 366m** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags near Nant-y-groes, west of Bala, Merionethshire, North Wales.
Lingulella davisi.
- 366n** [U. S. National Museum]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Lower *Lingula* flags at Portmadoc, Merionethshire, North Wales.
Lingulella davisi.
- 366o** [McCoy, 1854, p. 254]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: "Bala schists" at Bryn Melyn, near Bala, Merionethshire, North Wales.
Lingulella davisi.
- 366p** [Davidson, 1866, p. 57]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper Tremadoc beds at Deudraeth, Merionethshire, North Wales.
Lingulella davisi.
- 366q** (references follow species). (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper Tremadoc beds at Garth, opposite Portmadoc, Merionethshire, North Wales.
Lingulella davisi [Davidson, 1866, p. 57].
Lingulella lepis [Davidson, 1866, p. 54].
- 366r** [U. S. National Museum]. (For stratigraphic position and association, see p. 135.) Upper Cambrian: Shales 2 miles (3.2 km.) north of Builth, Brecknockshire, South Wales.
Lingulella davisi.
- 366s** [U. S. National Museum]. (See 366a.) (For stratigraphic position and association, see p. 135.) Upper Cambrian: Upper *Lingula* flags 5 miles (8 km.) east of Pfestiniog, Merionethshire, North Wales.
Orusia lenticularis.
- 367** [U. S. National Museum]. Lower Cambrian: Conglomerate and limestone, Troy, Rensselaer County, N. Y.
*Lingulella schucherti.
Microdiscus schucherti.
Protypus hitchcocki (Whitfield).
These species may be from widely different localities.
- 367a** [U. S. National Museum]. (See 38.) Lower Cambrian: Limestone about a third of a mile (0.5 km.) south of John Hulett's farmhouse, 3 miles (4.8 km.) west of South Granville, and 4.5 miles (7.2 km.) southwest of Granville, Fort Ann quadrangle (U. S. G. S.), Washington County, N. Y.
Billingsella salemensis.
- 367b** [U. S. National Museum]. Lower Cambrian: Sandstone at Lansingburg, north of Troy, Cohoes quadrangle (U. S. G. S.), Rensselaer County, N. Y.
Billingsella salemensis??.
Scenella sp.
- 367c** [U. S. National Museum]. Ordovician: Beekmantown limestone, Division A, quarry near the northwest suburbs of Ticonderoga, Essex County, N. Y.
*Lingulella (Lingulepis) acuminata sequens.
- 367d** (references follow species). Middle Cambrian: Limestones near Stissing, Dutchess County, N. Y.
*Micromitra (Paterina) stissingensis [Dwight, 1889, p. 145]. | *Leperditia ebenina [Dwight, 1889, p. 144].
Hyolithes billingsi? [Dwight, 1889, p. 143]. | *Olenoides stissingensis [Dwight, 1889, p. 147].
- 367e** [Dwight, 1886, p. 205]. Upper Cambrian: Shaly limestones 850 feet (259.1 m.) southerly from the southwest corner of the driving park and 2,200 feet (670.6 m.) west of the road leading southerly from the same, about 1 mile (1.6 km.) southwest of Vassar College, near Poughkeepsie, Dutchess County, N. Y.
Lingulella (Lingulepis) acuminata.
- 367f** [U. S. National Museum]. Upper Cambrian: Sandstone at French Creek, 1 mile (1.6 km.) east of Keeseville, Essex County, N. Y.
Lingulella prima.
- 367g** [U. S. National Museum]. Upper Cambrian: Sandstone in the bed of the brook in the suburbs of Port Henry, Essex County, N. Y.
Lingulella prima.
- 367h** [U. S. National Museum]. Upper Cambrian: Sandstone at Rosses Bridge, 4 miles (6.4 km.) west of Essex village, Essex County, N. Y.
Lingulella prima.

- 367i** [Hall, 1847, p. 290]. Lower Cambrian: Shales near Troy, Rensselaer County, N. Y.
**Botsfordia caelata*.
- 367j** [U. S. National Museum]. (See 108.) Upper Cambrian: Sandstones 3 miles (4.8 km.) south of Poughkeepsie, Dutchess County, N. Y.
Lingulella (*Lingulepis*) *acuminata*.
- 367k** [U. S. National Museum]. (See 109.) Upper Cambrian: Sandstone at Deweys Bridge, Washington County, N. Y.
Lingulella (*Lingulepis*) *acuminata*.
- 367l** [U. S. National Museum]. Cambrian: Shales 0.75 mile (1.2 km.) southwest of Hillsdale, Fort Ann quadrangle (U. S. G. S.), Washington County, N. Y. (L. M. Prindle, 1895).
Obolus sp.
- 368** (references follow species). Middle Cambrian: Quartzitic sandstone in the Pepper Mountains, near Sandomierz on the Vistula, Russian Poland.
Obolus apollinis (U. S. National Museum).
**Lingulella siemiradzki* (U. S. National Museum).
Lingula cf. *crassa* [Gurich, 1896, p. 214]=*Lingulella* *siemiradzki*.
Paradoxides cf. *tessini* [Gurich, 1896, p. 17].
- | | |
|--|------------------------------------------------------|
| | <i>Paradoxides bohemicus</i> [Gurich, 1896, p. 17]. |
| | <i>Agnostus fallax</i> [Gurich, 1896, p. 17]. |

| | <i>Liostracus linnarssoni</i> [Gurich, 1896, p. 17]. |
- 368a** [Siemiradzki, 1886, p. 672]. Gray sandstone of unknown stratigraphic position or age in the Polnischen Mittelgebirge, north of Sandomierz on the Vistula, Russian Poland.
Obolus (*Mickwitzella*) *siluricus*.
- 369** [U. S. National Museum]. (For stratigraphic position and association, see p. 137.) Upper Cambrian: Sandstone in the Elvins formation in the eastern limits of the town of Flat River, St. Francois County, Mo.
**Obolus ismene*.
Lingulella texana.
- | | |
|--|--------------------------------|
| | <i>Linnarssonella girtyi</i> . |
| | <i>Eoorthis indianola</i> . |
- 369a** [U. S. National Museum]. (For stratigraphic position and association, see p. 137.) Middle Cambrian: Limestone in or just beneath the "Edgewise beds" near Elvins, 6 miles (9.6 km.) south of Bonneterre, St. Francois County, Mo.
Eoorthis wichitaensis.
- 369b** [U. S. National Museum]. Upper Cambrian: Limestone near Potosi, Washington County, Mo.
Eoorthis indianola.
- 369c** [U. S. National Museum]. (For stratigraphic position and association, see p. 137.) Upper Cambrian: Dolomite above the "Edgewise beds" in a railroad cut 0.5 mile (0.8 km.) southwest of Elvins, 6 miles (9.6 km.) south of Bonneterre, St. Francois County, Mo. (E. O. Ulrich).
Billingsella major?.
- 369d** [U. S. National Museum]. (For stratigraphic position and association, see p. 137.) Upper Cambrian: Upper portion of the Elvins formation 2.5 to 3 miles (4 to 4.8 km.) north of Caledonia, Washington County, Mo.
Billingsella coloradoensis.
- 369e** [U. S. National Museum]. (For stratigraphic position and association, see p. 137.) Upper Cambrian: Sandstone on Big River, near Montana, Iron County, Mo.
Billingsella coloradoensis.
- 369f** [Walcott, 1891b, p. 341]. (For stratigraphic position and association, see p. 137.) Middle Cambrian: Limestone at Fredericktown, Madison County, Mo.
Obolus lamborni.
- 369g** [U. S. National Museum]. (For stratigraphic position and association, see p. 137.) Middle Cambrian: Shales at Bonneterre, St. Francois County, Mo.
Lingulella desiderata.
- 369h** [U. S. National Museum]. (For stratigraphic position and association, see p. 137.) Middle Cambrian: Shale at Mine Lamotte, Madison County, Mo. (C. D. Walcott and F. B. Meek).
Obolus lamborni.
- 372** [U. S. National Museum]. (See 8d.) (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale at Upper Leitches Creek, eastern Cape Breton, Nova Scotia.
Lingulella concinna.
- 372a** [U. S. National Museum]. (See 10m.) (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale 2 miles (3.2 km.) south of the Boisdale road from Upper Leitches Creek, eastern Cape Breton, Nova Scotia.
Lingulella concinna.

- 372b** [U. S. National Museum]. (See 3p.) (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale in ravine 0.5 mile (0.8 km.) north of McMullins, on the crossroad to Boisdale railroad station, eastern Cape Breton, Nova Scotia.
Lingulella concinna.
- 372c** [U. S. National Museum]. (See 3o.) (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale in ravine east of the railroad, just south of Barachois post office, eastern Cape Breton, Nova Scotia.
Lingulella concinna.
- 372d** [U. S. National Museum]. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shale on McAdam shore, East Bay, east of Bras d'Or Lake, eastern Cape Breton, Nova Scotia.
Lingulella concinna.
- 372e** [Matthew, 1903, p. 50]. (For stratigraphic position and association, see p. 131.) Upper Cambrian: Shales on McMullins Brook, near McLeod Brook (=Barachois River), eastern Cape Breton, Nova Scotia, Canada.
Monobolina refulgens.
Schizambon priscus.
- 372f** [U. S. National Museum]. (For stratigraphic position and association, see p. 134.) Middle Cambrian: Shales on Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia.
Lingulella (Lingulepis) longinervis.
- 374** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Middle Cambrian: In the suburbs of and 4 and 11 miles (6.4 and 17.7 km.) north-northeast of Knoxville, Knox County, Tenn.
Lingulella similis.
- 374a** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Limestone 2 miles (3.2 km.) south of Coal Creek, Anderson County, Tenn.
Dicellomus appalachia.
- 374b** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shale 1.25 miles (2 km.) from Rogersville, on the road to Powell, near the line between the Morristown and Greeneville quadrangles (U. S. G. S.), Hawkins County, Tenn.
Dicellomus appalachia.
- 374c** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Sandy shale (Nolichucky?) [Campbell, 1899, p. 3] 8 miles (12.8 km.) northeast of Shipleys, near the line between the Roan Mountain and Bristol quadrangles (U. S. G. S.), Sullivan County, Tenn.
Dicellomus appalachia.
- 374d** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shale 2 miles (3.2 km.) north of Rotherwood, Hawkins County, Tenn. (Cooper Curtice).
Lingulella (Lingulepis) acuminata.
- 374e** [U. S. National Museum]. (For stratigraphic position and association, see p. 147.) Middle Cambrian: Shales collected near the state line, 2.25 miles (3.6 km.) north of Peltier, Estillville quadrangle (U. S. G. S.), Sullivan County, Tenn. (M. R. Campbell).
Obolus willisi.
- 386** [Gagel, 1890, p. 34]. Passage beds between the Upper Cambrian and the Ordovician: Drift blocks of *Ceratopyge* limestone near Belschwitz, East Prussia, Germany.
Eoorthis daunus.
- 386a** [Gagel, 1890, p. 34]. Passage beds between the Upper Cambrian and the Ordovician: Drift blocks of "Glauconite limestone" near Prussian Holland, 90 miles (145 km.) south-southwest of Königsberg, East Prussia, Germany.
Orthis christianiaë = Eoorthis daunus?.
- 386b** (references follow species). Passage beds between the Upper Cambrian and Ordovician: Drift blocks of "Glauconite limestone" near Wehlau, 30 miles (48.3 km.) east of Königsberg, East Prussia, Germany.
Obolus (Acrisis) antiquissimus [Gagel, 1890, p. 22].
Orthis christianiaë [Gagel, 1890, p. 34] = Eoorthis daunus? } These species may occur in different blocks of limestone.
- 386c** [Roemer, 1885, p. 23 (270)]. Upper Cambrian: Drift boulder found near Lyck, East Prussia, Germany.
Obolus apollinis.
- 386d** [Roemer, 1885, p. 23 (270)]. Upper Cambrian: Drift boulder found near Danzig, West Prussia, Germany.
Obolus apollinis.
- 386e** [Roemer, 1885, p. 33 (280)]. Upper Cambrian: Drift boulders of gray bituminous limestone between Vistula and Elbe rivers, in Schleswig-Holstein and Mecklenburg-Schwerin, Germany.
Orusia lenticularis.
Parabolina spinulosa.

- 386f** [Roemer, 1885, p. 34 (281)]. Upper Cambrian: Drift bowlders of gray bituminous limestone near Wismar, Mecklenburg-Schwerin, Germany.
Orusia lenticularis.
- 386g** [Roemer, 1885, p. 34 (281)]. Upper Cambrian: Drift bowlders of gray bituminous limestone near Rostock, Mecklenburg-Schwerin, Germany.
Orusia lenticularis.
- 386h** [Roemer, 1885, p. 34 (281)]. Upper Cambrian: Drift bowlders of gray bituminous limestone near Meseritz, Province of Posen, Germany.
Orusia lenticularis.
- 386i** (references follow species). (For stratigraphic position and association, see p. 143.) Ordovician: Drift bowlder of *Echinosphærites* limestone near Wehlau, 30 miles (48.3 km.) east of Königsberg, East Prussia, Germany.
Siphonotreta unguiculata [Gagel, 1890, p. 23].
Siphonotreta verrucosa [Gagel, 1890, p. 22].
- 386j** [Gagel, 1890, p. 23]. (For stratigraphic position and association, see p. 143.) Ordovician: Drift bowlder of *Echinosphærites* limestone at Belschwitz, East Prussia, Germany.
Siphonotreta unguiculata.
- 386k** [Gagel, 1890, p. 22]. (For stratigraphic position and association, see p. 143.) Ordovician: Drift bowlder of *Echinosphærites* limestone near Wormditt, East Prussia, Germany.
Siphonotreta unguiculata.
Siphonotreta verrucosa.
- 386l** [Gagel, 1890, p. 22]. (For stratigraphic position and association, see p. 143.) Ordovician: Drift bowlder of *Echinosphærites* limestone near Marienwerder, West Prussia, Germany.
Siphonotreta unguiculata.
Siphonotreta verrucosa.
- 389** [Kayser, 1876, p. 8]. Upper Cambrian: Sandstone at Salta, Province of Salta, Argentina, South America.

- 396n** [Mickwitz, 1896, p. 213]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: White limestone between the "glaconite limestone" and the sandy representative of the "*Vaginatum* limestone" at Leppiko, near Leetz, on the eastern side of the Baltischport peninsula, about 25 miles (40.3 km.) west of Reval, Government of Esthonia, Russia.
Obolus (*Acritis*) *antiquissimus*.
- 396o** [Mickwitz, 1896, p. 213]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: "Glaconite limestone" in the entire western part of the east Baltic region, Government of Esthonia, Russia.
Obolus (*Acritis*) *antiquissimus*.
- 396p** [Mickwitz, 1896, p. 213]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: Strata between the "lower lenticular layer" and the "*Vaginatum* limestone" proper at Nömmeweske, near Palms, Government of Esthonia, Russia.
Obolus (*Acritis*) *antiquissimus*.

- 396q [Schmidt, 1888, p. 24]. (For stratigraphic position and association, see p. 144.) Lower Cambrian: Upper boundary of the blue clay with the Fucoïd sandstone (the "*Mickwitzia* conglomerate" [Schmidt, 1888, p. 24]), at Reval, Government of Esthonia, Russia.
Mickwitzia monilifera.
- 396r [Schmidt, 1888, p. 24]. (For stratigraphic position and association, see p. 144.) Lower Cambrian: In the "upper strata" at Streitberg, near Reval, Government of Esthonia, Russia.
Mickwitzia monilifera.
- 396s [Schmidt, 1888, p. 24]. (For stratigraphic position and association, see p. 144.) Lower Cambrian: In loose blocks on Kosch Brook near Likkat, near Reval, Government of Esthonia, Russia.
Mickwitzia monilifera.
- 396t [Schmidt, 1888, p. 24]. (For stratigraphic position and association, see p. 144.) Lower Cambrian: At the sandstone capes of Ziegelskoppel, Kakkomaggi (also Rocca al Mare), near Reval, Government of Esthonia, Russia.
Mickwitzia monilifera.
- 396u [Schmidt, 1888, p. 24]. (For stratigraphic position and association, see p. 144.) Lower Cambrian: In loose blocks on the lower course of Jaggowal Brook, about 20 miles (32.2 km.) east-southeast of Reval, Government of Esthonia, Russia.
Mickwitzia monilifera.
Traces of *Olenellus*.
- 396v [Schmidt, 1888, p. 24, and U. S. National Museum]. (For stratigraphic position and association, see p. 144.) Lower Cambrian: At the upper boundary of a dolomitic sandstone with which the *Olenellus* stratum begins, below the cement factory on Kunda Brook, Government of Esthonia, Russia.
Mickwitzia monilifera.
Traces of *Olenellus*.
- 396w [Schmidt, 1888, p. 24]. (For stratigraphic position and association, see p. 144.) Lower Cambrian: In the glauconitic sands above the main mass of the clay, below the cement factory on Kunda Brook, Government of Esthonia, Russia.
Mickwitzia monilifera.
- 396x [Eichwald, 1843, p. 146]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: In the chlorite-bearing sands in the limestone beds at Baltischport, about 30 miles (48 km.) west of Reval, Government of Esthonia, Russia.
Obolus (*Acritis*) antiquissimus.
Obolus (*Mickwitzella*) siluricus.
- 396y [Eichwald, 1843, p. 147]. (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: In the chlorite-bearing sands in the limestone beds at Reval, Government of Esthonia, Russia.
Obolus (*Acritis*) antiquissimus.
Obolus (*Mickwitzella*) siluricus.
- 396z [Kutorga, 1848, p. 283]. (See 336g.) (For stratigraphic position and association, see p. 143.) Passage beds between the Upper Cambrian and the Ordovician: Limestone in the vicinity of Zarskoe Selo, Government of St. Petersburg, Russia.
Obolus (*Acritis*) antiquissimus.

Localities C1-C75, Carnegie Institution of Washington Expedition to China.^a

C1 (just above C4, same section; just below C2, same section; about 75 feet below C62, which occurs at a locality 3 miles east; about same horizon as C10, different section; about 150 feet below C12, same section). Middle Cambrian: Lower shale member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 40 (part of the third list of fossils), and fig. 10 (bed 4), p. 38], 2 miles (3.2 km.) south of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-27-1903).

^a See the explanatory paragraphs on pp. 160-161.

- C2** (above C4, same section; just above C1, same section; about same horizon as C10, different section). Middle Cambrian: Lower shale member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 40 (part of the third list of fossils), and fig. 10 (beds 4 and 5), p. 38], 2 miles (3.2 km.) south of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-30-1903).
- Obolus* (*Westonia*) *blackwelderi*.
Acrotreta pacifica.
Protospongia chloris Walcott.
Hyalithes cybele Walcott.
Orthotheca cyrene dryas Walcott.
Agnostus chinensis Dames.
Dorypyge bispinosa Walcott.
Anomocare latelimbatum Dames.
- Anomocarella albion* Walcott.
Anomocarella biston (Walcott).
Anomocarella chinensis Walcott.
Coosia? *daunus* (Walcott).
Lisania agonius (Walcott).
Dolichometopus derceto Walcott.
Dolichometopus deois Walcott.
Lonchocephalus tellus (Walcott).
- C3** (about 100 feet above the horizon of C60, different section; about 175 feet below the horizon of C8, different sections). Lower Cambrian: Lower part of the Manto shale formation [Blackwelder, 1907a, p. 28 (list of fossils at bottom of page), and fig. 8a (bed 20), p. 28], on the southeast slope of Hulushan, 2.5 miles (4 km.) southwest of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-30-1903).
- **Billingsella richthofeni*.
Stenotheca rugosa chinensis Walcott.
Hyalithes delia Walcott.
- Redlichia nobilis* Walcott.
Ptychoparia (*Emmrichella*) *constricta* (Walcott.)
- C4** (just below C1, same section; same horizon as C57, different section). Middle Cambrian: In limestone nodules at the base of the lower shale member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 40 (second list of fossils), and fig. 10 (bed 4), p. 38], 3 miles (4.8 km.) southwest of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-27-1903).
- **Acrothele matthewi eryx*.
Acrotreta pacifica.
Protospongia chloris Walcott.
Platyceras chronus Walcott.
Hyalithes cybele Walcott.
Orthotheca delphus Walcott.
- Agnostus chinensis* Dames.
Anomocarella albion Walcott.
Anomocarella chinensis Walcott.
Lisania alala (Walcott).
Dolichometopus alceste Walcott.
Dolichometopus deois Walcott.
- C5** (about 25 feet above C8, same section; about 40 feet below C63, same section). Middle Cambrian: Lower limestone member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 39 (first list of fossils), and fig. 8a (bed 30), p. 29], 3.2 miles (5.1 km.) southwest of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-23-1903). On the figure this bed is placed as occurring below the line dividing the Manto from the Kiulung, but on the basis of the fauna contained in the limestone it is referred to the base of the Kiulung. The text (p. 39) places the boundary between the Kiulung and the Manto, 15 feet below C5.
- Micromitra* (*Iphidella*) *pannula ophirensis*.
**Acrotreta pacifica*.
Globigerina? *mantoensis* Walcott.
Inouyia divi (Walcott).
- Anomocare butes* Walcott.
Anomocare sp.
Dolichometopus sp.
- C6** (about 120 feet above C12, same section; about 20 feet below C61, same section). Middle Cambrian: Thin platy limestone in the upper shale member of the Kiulung group just below the Chaumitien limestone [Blackwelder, 1907a, pp. 37 and 41 (second list of fossils), and fig. 10 (bed 12), p. 38], 2.5 miles (4 km.) southwest of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-25-1903).
- **Acrothele minuta*.
**Obolus* (*Westonia*) *blackwelderi*.
**Dicellomus parvus*.
Agnostus douvillei Bergeron.
Blackwelderia sinensis (Bergeron).
Drepanura ketteleri Monke.
Drepanura premesnili Bergeron.
Ptychoparia (*Emmrichella*) *bromus* (Walcott).
- Redlichia* sp. undt. Walcott.
Shantungia spinifera Walcott.
Stephanocare? *monkei* Walcott.
Stephanocare richthofeni Monke.
Stephanocare sinensis (Bergeron).
Stephanocare? sp. undt. Walcott.
Liostracina krausei Monke.
- C7** (just above C9, same section; about same horizon as C52, different sections; about 200 feet below C10, same section). Middle Cambrian: Lower limestone member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 39 (last list of fossils), and fig. 8a (bed 33), p. 29], 2.2 miles (3.5 km.) southwest of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-23-1903).
- Lingulella damesi*.
Lingulella (*Lingulepis*) *eros*.
Inouyia abaris (Walcott).
Inouyia titiana (Walcott).
- Agraulos dolon* Walcott.
Anomocarella subrugosa (Walcott).
Anomocarella thraso (Walcott.)

- C9** (just below C7, same section; about 25 feet above C63, same section; about same horizon as C52, different sections). Middle Cambrian: Lower limestone member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 39 (third list of fossils), and fig. 8a (bed 33), p. 29], 3 miles (4.8 km.) southwest of Yenchuang, Sintai district, Shantung, China (? , 11-27-1903).
- **Micromitra* (*Paterina*) *labradorica orientalis*. | *Coosia decelus* (Walcott).
Inouyia abaris (Walcott). | *Anomocare minus* Dames.
- C10** (about 200 feet above C7, same section; about same horizon as C1, C2, and C4, different section). Middle Cambrian: Lower shale member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 40 (part of the third list of fossils), and fig. 8a (bed 35), p. 29], about 3 miles (4.8 km.) southwest of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder, 11-23-1903).
- **Lingulella damesi*.
Anomocarella temenus (Walcott).
Menocephalus sp. undt. Walcott.
- C12** (about 120 feet below C6, same section; about 75 feet above C62, same section but at a locality 3 miles east; C13 includes the horizon represented by C12; about 150 feet above C1, same section). Middle Cambrian: Gray limestone near the top of the middle limestone member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 41 (part of first list of fossils), and fig. 10 (bed 7), p. 38], 3.25 miles (5.2 km.) southwest of Yenchuang, Sintai district, Shantung, China (Eliot Blackwelder and Li San, 11-25-1903).
- Acrotreta pacifica*. | *Blackwelderia alastor* (Walcott).
Inouyia acalle (Walcott). | *Anomocarella tutia* (Walcott).
Lisania ajax (Walcott). | *Pterocephalus asiatica* Walcott.
Damesella blackwelderi Walcott. | *Teinistion alcon* (Walcott).
- C17** (about 180 feet below C23, same section; about 35 feet above C20, adjacent sections; about 160 feet below C28, adjacent sections). Lower Cambrian: Ferruginous limestone nodules in the brown sandy shales at the top of the Manto shale [Blackwelder, 1907a, p. 27 (list of fossils at top of page) and fig. 6 (bed 15), p. 25], at Changhia, Shantung, China (Eliot Blackwelder, 10-31-1903).
- Obolella asiatica*. | *Ptychoparia impar* Walcott.
Ptychoparia aclis Walcott. | *Ptychoparia granosa* Walcott.
- C20** (about 15 feet above C31, same section; about 35 feet below C17, different sections). Lower Cambrian: Central part of the Mauto shale formation [Blackwelder, 1907a, p. 26 (last list of fossils) and fig. 6 (bed 14), p. 25], on the west side of an isolated butte 1 mile (1.6 km.) south of Changhia, Shantung, China (Eliot Blackwelder, 10-27-1903).
- Billingsella richthofeni*?.
Ptychoparia aclis Walcott.
Ptychoparia (*Emmrichella*) *mantoensis* (Walcott).
- C22** (about same horizon as C19, C24, and C26, same section; above C18, same section). Middle Cambrian: Changhia limestone in upper oolitic portion [Blackwelder, 1907a, pp. 22 and 33 (part of last list of fossils)], at Changhia, Shantung, China (Eliot Blackwelder, 10-29-1903).
- **Acrotreta lisani*. | *Lisania bura* (Walcott).
Hyalolithes cybele Walcott. | *Menocephalus admeta* Walcott.
Anomocarella temenus (Walcott). | *Menocephalus acantha* (Walcott).
Lisania alala (Walcott).
- C23** (about 180 feet above C17, same section; about 25 feet above C28, different sections). Middle Cambrian: Upper part of thin-bedded gray oolitic limestone at the base of the Changhia formation [Blackwelder, 1907a, p. 32 (second list of fossils) and fig. 6 (bed 20), p. 25], 50 feet below the base of the cliffs 1 mile (1.6 km.) east-southeast of Changhia, Shantung, China (Eliot Blackwelder, 10-27-1903).
- Acrothele rara*? | *Anomocarella tatián* (Walcott).
Orthotheca daulis Walcott. | *Ptychoparia* (*Emmrichella*) *eripia* (Walcott).
Agraulos abrota Walcott. | *Ptychoparia* (*Emmrichella*) *theano* (Walcott).
- C24** (about same horizon as C19, C22, and C26, same section; above C18, same section; about same horizon as C25, different section). Middle Cambrian: Near top of black oolitic group in the uppermost layers of the Changhia formation [Blackwelder, 1907a, p. 33 (part of last list of fossils)], 2 miles (3.2 km.) east of Changhia, Shantung, China.
- Acrotreta* cf. *pacifica*. | *Dolichometopus dirce* Walcott.
Agnostus sp. undt. | *Dorypyge richthofeni* Dames.
Inouyia divi (Walcott).

C26 (about same horizon as C19, C22, and C24, same section; above C18, same section). Middle Cambrian: Upper portion of the Changhia limestone, near top of black oolitic group [Blackwelder, 1907a, p. 33 (part of last list of fossils)], 2 miles (3.2 km.) north-northeast of Changhia, Shantung, China (Eliot Blackwelder, 10-29-1903).

Eoorthis sp. undt.

Anomocare? *daulis* Walcott.

Crepicephalus *damia* Walcott.

C28 (about 200 feet above C20, same section; about 160 feet above C17, adjacent sections; about 25 feet below C23, different sections). Middle Cambrian: Thin-bedded oolitic limestone at the base of the Changhia limestone [Blackwelder, 1907a, p. 32 (first list of fossils) and fig. 6 (bed 20), p. 25], just above the shales in the face of the cliff 1 mile (1.6 km.) east-southeast of Changhia, Shantung, China (Eliot Blackwelder, 10-29-1903).

**Eoorthis* *agreste*.

Anomocarella *tenes* (Walcott).

Anomocarella *texeus* (Walcott).

Inouyia *thisbe* Walcott.

Bathyriscus.

C32 (see also C32', other drift blocks at the same locality). Middle Cambrian: A fine-grained bluish-black limestone boulder believed to have come from the lower part of the Kisinling limestone [Blackwelder, 1907b, p. 272], collected in river drift 1 mile (1.6 km.) south of Chonpinghien, on Nankiang River, southern Shensi, China (Bailey Willis and Eliot Blackwelder, 5-28-1904).

Obolus *shansiensis*.

Dicellomus *parvus*.

Acrotreta *shantungensis*.

Orthotheca *doris* Walcott.

Microdiscus *orientalis* Walcott.

Aluta *bergeroni* (Walcott).

Aluta *enyo* (Walcott).

Aluta *eris* (Walcott).

Aluta *fragilis* (Walcott).

Aluta *sterope* (Walcott).

Aluta *woodi* (Walcott).

C32' (see C32, another drift block at the same locality). Lower Cambrian: A limestone boulder collected in river drift 1 mile (1.6 km.) south of Chonpinghien, on Nankiang River, southern Shensi, China (Bailey Willis and Eliot Blackwelder, 5-28-1904).

**Obolella* *asiatica*.

Hyalolithes sp. undt.

C36 (about same horizon as C45, different section; about same horizon as C50, same section; above C68, same section; about same horizon as C47, same section). Upper Cambrian: Upper part of the Chaumitien limestone [Blackwelder, 1907a, p. 36 (part of third list of fossils), and fig. 9 (bed 2), p. 35], at Chaumitien, Changhia district, Shantung, China (Eliot Blackwelder, 10-22-1903).

Billingsella *pumpellyi*.

Anomocarella *baucis* Walcott.

C37 (about same horizon as C72, same section; about 50 feet above C71, same section; about 200 feet below C73, same section; about 225 feet below C74, same section). Middle Cambrian: Upper part of the Kichou limestone, in dense black limestone nodules in green-gray shales 10 feet below the base of the cliff limestone, 8 miles (12.8 km.) south of Tinghianghien, Shansi, China (Eliot Blackwelder, 2-24-1904). The fossils from this locality are not listed, but the presence of Cambrian strata at the locality is mentioned by Willis and Blackwelder [1907, p. 146].

**Obolus* *shansiensis*.

Acrotreta *shantungensis*.

Anomocare *megalurus* (Walcott).

C54 (same horizon as C41, C49, and C56; about same horizon as C34 and C38, different sections). Upper Cambrian: Lower part of Chaumitien limestone [Blackwelder, 1907a, p. 42 (part of last list of fossils)], near top of limestone knoll 0.66 mile (1.1 km.) west of Tsinan, Shantung, China (Eliot Blackwelder, 11-6-1903).

**Obolus* *matinalis?*

Eoorthis *pagoda*.

Syntrophia *orthia*.

Illænurus *canens* Walcott.

Illænurus sp. undt.

Pterocephalia *busiris* Walcott.

Ptychaspis *ceto* Walcott.

Ptychaspis sp. undt.

C56 (same horizon as C41, C49, and C54). Upper Cambrian: Lower part of Chaumitien limestone 25 feet below the top of Pagoda Hill [Blackwelder, 1907a, p. 42 (part of last list of fossils)], 1 mile (1.6 km.) west of Tsinan, Shantung, China (Eliot Blackwelder and Li San, 11-6-1903).

ZOOLOGICAL DISCUSSION.

The zoological relations of the Cambrian Brachiopoda, or their consideration from the paleozoologist's standpoint, are discussed under four general headings: (1) Characters of the shells, including the terminology adopted in describing them; (2) distribution in Cambrian strata; (3) evolution; and (4) classification. Under evolution no general description of the evolution of the Brachiopoda is attempted, nor is the life history of the living species treated. The discussion is limited to certain observations on the Cambrian species and genera that appear to add to our general knowledge of the subject.

TERMINOLOGY.

GENERAL STATEMENT.

Except for the muscle scars of the inarticulate brachiopods, the terms used in the description of genera and species are largely those defined by Schuchert [1897, pp. 73-75]. For the Atremata and Neotremata the terminology proposed by William King [1873, pp. 5 and 6] is adopted, and for the Protremata that used by Hall and Clarke [1892a, pp. 183-188] and given

under the terminology of Schuchert [1897, pp. 73-77]. I agree with Hall and Clarke [1892c, p. 21] that the terminology of the English authors has claims for its adoption. F. Blochmann [1900, p. 108] has proposed a set of terms for the muscles of the inarticulate brachiopods that has much to commend it. The terminology of Albany Hancock [1859, p. 800] has been extensively used by authors. The numbers in this correspond to the numbers given the terminology of King, Schuchert, and Blochmann.

Terminology of Hancock [1859, p. 800].

| Inarticulates: | Articulates: |
|-------------------------|----------------------------|
| 1. Anterior oclusors. | 1. Anterior oclusors. |
| 2. Posterior oclusors. | 2. Posterior oclusors. |
| 3. Divaricator. | 3. Accessory divaricators. |
| 4. Central adjustors. | 4. } Ventral adjustors. |
| 5. External adjustors. | 5. } |
| 6. Posterior adjustors. | 6. Dorsal adjustors. |
| 7. Peduncular. | 7. Peduncular. |

Terminology of King [1873, pp. 5-6].

| | |
|----------------------|----------------------|
| 1. Anterior lateral. | 4. Transmedians. |
| 2. Centrals. | 5. Outside laterals. |
| 3. Umbonal. | 6. Middle laterals. |

Terminology of Schuchert [1897, pp. 73-75].

| | |
|----------------|-----------------------------|
| 1. Retractors. | 5. Protractors (externals). |
| 2. Adductors. | 6. Protractors (middles). |
| 3. Pedicle. | 7. Diductors. |
| 4. Rotators. | |

Terminology of Blochmann [1900, p. 108].

| | |
|-----------------------|-----------------------|
| 1. Lateralis. | 4. Obliquus internus. |
| 2. Oclusor anterior. | 5. Obliquus externus. |
| 3. Oclusor posterior. | 6. Obliquus medius. |

DEFINITIONS.

Adductor muscles (see Central muscles).—The term adductor is used in the description of the muscles of the Protremata.

Anterior lateral (retractor) muscles.—In the Atremata these extend from the outer lateral margins of the visceral area in the ventral valve to its anterior extremity in the dorsal valve, and serve to readjust the dorsal shell.

Anterior region.—That portion of the shell in front of the transverse axis and opposite the pedicle opening.

Apex.—The place of initial shell growth. It may be the most posterior portion of the valve or it may be situated near the transverse axis.

Apical callosity.—The thickened boss at the inner side of the apex of the ventral valve of *Acrotreta* and other neotrematous genera, through which the pedicle tube or foramen passes.

Area.—See Cardinal area.

Articulate brachiopods.—In the orders Protremata and Telotremata the valves articulate by means of teeth and sockets. In some Atremata rudimentary articulation is also developed. (See p. 307.)

Atremata.—Primitive inarticulate calcareophosphatic brachiopods with the pedicle emerging more or less freely between the two valves. For a more detailed description see "Classification of Cambrian Brachiopoda," page 321.

Brachia.—The fleshy, coiled or spiral, ciliated appendages of brachiopods serving in water circulation and respiration.

Brachiocale.—All of the anterior half of the valves outside of the anterior portion of the parietal band. (After King.)

Cardinal area.—A more or less well developed triangular area on each side of the delthyrium, distinctly set off from the general surface of the shell. It is best developed on the ventral

valve of articulate brachiopods, but is also present on the dorsal valve, and generally in a rudimentary condition in many inarticulate species. When the area is rudimentary it is often called a false or pseudo-area (Pl. II, figs. 1 and 7a; Pl. III, figs. 2a and 6b; Pl. V, figs. 1d at a; Pl. VI, figs. 1'' and 3b). The area of some of the inarticulate genera is frequently divided by a line between the delthyrium and the outer margin; in such areas the line is called the flexure line, owing to the slight interruption in the striæ of growth (Pl. VIII, fig. 1d at f), and the spaces separated by the flexure line are called the inner and outer lateral spaces of the area. (See *Deltidium* and *Foramen*, and p. 303.)

Cardinal extremities.—The terminations of the hinge line.

Cardinal muscle scar.—A large scar within which the posterior, anterior lateral, and transmedian muscles were attached.

Cardinal process.—A variously modified apophysis situated posteriorly at the center of the hinge of the dorsal valve in articulate brachiopods. To it are attached the diductor muscles, which by their contraction serve to open the valves anteriorly. (See p. 306.)

Cardinal slopes.—The inclined surfaces extending from the umbonal slopes to the hinge margins.

Central (adductor) muscles.—In the Protremata and Telotremata these muscles have their ventral insertion one on either side of the central axis, between the diductors. In passing to the dorsal valve they divide into four, and produce in that shell the two pairs of principal scars known as the anterior and posterior centrals. By contraction these muscles close the shell. In the Neotremata they are the essential muscles, the anterior centrals closing the valves, while the posterior pair serves to open the valves. In the Atremata there is a simple pair of centrals placed near the anterior extremity of the visceral area.

Chilidium.—A dorsal plate, in appearance similar to the *deltidium*, covering the exterior portion of the cardinal process in many Protremata. Its development does not begin until early neanic or later growth, and it is probably secreted by the dorsal mantle lobe. In the Atremata and Neotremata a similar plate, continuous with the dorsal cardinal region of the shell, is named the *pseudochilidium*. (See p. 306.)

Crura.—Processes on the dorsal hinge plate of the Telotremata and some Protremata, to which are attached the fleshy brachia and brachidia. These usually form the inner walls of the dental sockets, and may be supported by septal plates.

Cruralium.—The dorsal equivalent of the ventral spondylium. (See p. 309.)

Delthyrium.—The triangular aperture transecting medially the ventral cardinal area, or the posterior surface from the apex to the posterior margin of the ventral valve, through some portion of which the pedicle passes. It has also been termed the *fissure* or *foramen*. The delthyrium may or may not be closed either by a calcareous *deltidium* or a phosphatic *pseudodeltidium*. (See p. 305.)

Deltidium.—A plate more or less continuous with the cardinal margin of the ventral valve and covering the delthyrium in Atremata, Neotremata, and Protremata. When present in inarticulate brachiopods it is called the *pseudodeltidium*. In the Protremata, in which it is always more calcareous, thicker, and more sharply defined, it is called the *deltidium* or the *pseudochilidium*. (See p. 305.)

Dental plates.—Vertical plates supporting the teeth of the ventral valve in articulate brachiopods. (See p. 310.)

Dental sockets.—Excavations in the dorsal cardinal margin of articulate brachiopods, in which the teeth of the ventral valve articulate. The inner wall of the socket is elevated and forms the base of the crural plate.

Diductor muscles.—In the Protremata and Telotremata the principal pair of diductor muscles has the larger end attached to the ventral valve near the anterior edge of the visceral area, and the other end has its insertion on the anterior portion of the cardinal process. By contraction these muscles open the valves.

Dorsal valve.—Usually the smaller and imperforate valve and the one to which the brachia are always attached. *Brachial, hæmal, socket, and entering valves* are other terms more rarely employed.

Ephobic.—Designating the mature shell.

False area.—See Cardinal area.

Flexure line.—See Cardinal area.

Foramen.—A small circular passage through the deltidium, either below or at the apex of the ventral valve. Sometimes the foramen encroaches by pedicle abrasion on the umbo of the ventral valve. (See p. 314.)

Foraminal tube.—The pedicle opening through the ventral valve of neotrematous genera. (See Pl. LVIII, fig. 5b.)

Genital markings.—Radial markings or pits within the posterior portion of the visceral space, indicating the position and extent of the genitals.

Gerontic.—Designating old age. It is indicated in the ontogeny of many species of brachiopods by extreme thickness of the valves, obesity, or by numerous crowded growth lines near the anterior margin, a condition which sometimes produces truncation and absence of striæ at the margin. (See p. 315.)

Heart-shaped cavity.—Central depressed portion of visceral area (Mickwitz). (See Pl. VII, figs. 9, 11, and 12 at x; also figs. 1, 2, and 8.)

Hinge line.—The line along which articulation takes place. Also sometimes developed among inarticulate brachiopods.

Inarticulate brachiopods.—In the orders Atremata and Neotremata the valves do not, as a rule, articulate by means of teeth and sockets, as is the case in the articulate orders Protremata and Telotremata.

Lateral areas.—That portion of the shell on each side of the central axis.

Listrium.—In some Neotremata a plate closing the progressive track of the pedicle opening or pedicle cleft posterior to the apex of the ventral valve. (See p. 306.)

Longitudinal axis.—A median line through the shell from the beak to the opposite margin.

Median septum.—An internal vertical plate commonly developed along the longitudinal axis and between the muscles of the ventral valve. Sometimes there is also a dorsal median septum. Lateral septa are rarely developed.

Middle lateral muscle scar.—See Outside and middle lateral muscles.

Neanic.—Designating youthfulness, or the stage in which specific characters begin to develop.

Neotremata.—Circular or oval, more or less cone shaped, inarticulate calcareophosphatic brachiopods with the pedicle opening restricted throughout life to the ventral valve. For a more detailed description see "Classification of Cambrian Brachiopoda," page 323.

Nepionic.—Designating the smooth shell stage succeeding the protogulum.

Outside and middle lateral (protractor) muscles.—In the Obolidæ one pair has the ventral ends fastened at the anterior extremity of the visceral area, extending backward and inserted near the lateral margin of the dorsal valve, outside the transmedians. A second pair originates just behind the centrals of the ventral valve and is inserted posterior to the first pair. These muscles draw the dorsal valve forward.

Parietal band.—The point of attachment of the muscular wall surrounding the visceral area.

Pedicle.—The flexible muscular organ of the ventral valve by means of which brachiopods may be attached to extraneous objects.

Pedicle furrow.—The external furrow adjoining the foramen or pedicle opening in certain neotrematous genera. (See Pl. LXXXIII, figs. 1 and 2; Pl. LXXXIV, figs. 1 and 5c.)

Pedicle groove.—The median groove on the cardinal areas of the valves, formed by the pedicle extending through the posterior margin of the valves when they were closed.

Pedicle muscles.—In the Protremata and Telotremata one pair originates on the ventral valve at points just outside and behind the diductors and another on the dorsal valve behind the posterior centrals, while the opposite ends of both are attached to the pedicle. Besides these there is an unpaired muscle lying at the base of the pedicle, attaching it closely to the ventral valve.

Pedicle opening.—See Delthyrium.

Pedicle tube.—See Foraminal tube.

Platform.—An internal median thickening of the shell elevating the muscles. Seen in certain families of the Atremata and more rarely in the Neotremata. (See Spondylium and pp. 307 and 309.)

Pleurocæles.—Areas between the parietal band and the outer posterolateral margins. (After King.)

Posterior region.—That portion of the shell back of the transverse axis and toward the beak or apex.

Protegium.—The initial shell of brachiopods. It is smooth and of microscopic size, in outline being semicircular or arcuate and without cardinal areas.

Protractor muscles.—See Outside and middle lateral muscles.

Protremata.—Articulate calcareous brachiopods with the pedicle opening restricted to the ventral valve throughout life or during early growth. Pedicle aperture modified by the deltidium. Brachia unsupported by a calcareous skeleton but nearly always by a crura of variable length. For a more detailed description see "Classification of Cambrian Brachiopoda," page 325.

Pseudo-area.—See Cardinal area.

Pseudochilidium.—See Chilidium.

Pseudocruralium.—Dorsal equivalent of pseudospondylium.

Pseudodeltidium.—The convex medial portion continuous with the ventral cardinal areas in Atremata and Neotremata. (See Deltidium.)

Pseudopedicle groove.—See Pedicle groove.

Pseudospondylium.—See Spondylium.

Retractor muscles.—See Anterior lateral muscles.

Septal plates.—Plates supporting the crural processes, also known as *crural plates*. (See p. 310.)

Sessile spondylium = Pseudospondylium.

Splanchnocæle.—The area within the parietal band. (After King.)

Spondylium.—A plate in some articulate brachiopods, mainly the Pentameracea, formed by the union of converging dental plates, to the upper surface of which are attached the adductor, diductor, and pedicle muscles. The spondylium may rest upon the ventral valve or may be supported by a median septum. The spondylium appears to be first indicated in the articulates by a thickening of the shell of the ventral valve beneath the umbonal region so as to form an area upon which all the muscles of the valve have their points of attachment. In *Billingsella* this is beautifully illustrated by *B. exprorecta* (Pl. LXXXVIII, figs. 1d, 1e, and 2a) and *B. plicatella* (Pl. LXXXVI, figs. 3i, 3k, and 3m). In its development the spondylium is foreshadowed in the Atremata by the so-called platform of *Elkania* (Pl. LI, figs. 1 and 1a) and by the still more primitive form in *Obolus* (Pl. VI). For the purpose of reference the rudimentary spondylia attached directly to the inner surface of the valve, as in *Billingsella*, may be called pseudo-spondylia (sessile spondylia, Ulrich), and those free or supported by a septum or septa, spondylia. In the Atremata the homologous equivalent has been known as the platform. In *Obolus*, *Elkania*, etc., there is sometimes developed in the dorsal valve a plate similar in appearance to the spondylium, but different in origin; this is known as the cruralium. (See p. 307.)

Teeth.—Two processes of the ventral valve of articulate brachiopods, serving for articulation. (See p. 307.)

Telotremata.—Articulate Brachiopoda with the pedicle opening shared by both valves in nepionic and early neanic stages, usually confined to one valve in later stages, and becoming more or less modified by deltidial plates in ephebic stages. Brachia supported by calcareous crura, loops, or spiralia. Prodeltidium absent. (After Schuchert.)

Transmedian (rotator) muscles.—In the Obolacea these are situated posteriorly just in advance of the umbonal muscle, two on one side and one on the other. By their contraction the dorsal valve turns alternately, first in one direction and then in the other.

Transverse axis.—A line through the shell from right to left midway between the beak and anterior margin. (See Longitudinal axis.)

Trapezoidal area.—The area on each side of the heart-shaped cavity in *Obolus* in which the outside and middle lateral scars and central muscle scars were attached. (See Pl. VII, figs. 10 and 12.)

Umbo.—The elevated or prominent portion of the valve anterior to the apex.

Umbonal cavity.—The hollow space in the interior of the shell beneath the umbo.

Umbonal muscle.—A single muscle situated in the umbonal region of most *Atremata*. By its contraction the valves are opened anteriorly. In *Obolus* this muscle divides toward the ventral valve.

Umbonal slopes.—The inclined surfaces about the umbo and opposite the cardinal slopes.

Vascular (pallial) sinuses.—Two convergent or divergent primary sinuses of the circulatory system, traversing the mantle and originating in the posterior medial region. They usually have numerous secondary (lateral and peripheral) branches, and both often leave impressions in the shell. (See p. 311.)

Ventral valve.—Usually the larger valve situated on the ventral side of the animal. Among articulate brachiopods the valve is usually easily distinguished by the presence of a delthyrium or pedicle opening through which the pedicle is protruded. In many atrematous genera the ventral valve is not readily distinguished. When the shell is cemented to foreign bodies it is always by the ventral valve. It is usually the larger and deeper of the two valves. *Pedicle, larger, dental, neural, and receiving valves* are synonymous terms.

Visceral area.—The posterior region of the interior of the valves between the pallial sinuses; in general the immediate area of the median muscle tracks.

Visceral cavity.—Visceral area.

THE BRACHIOPOD SHELL.

STRUCTURE.

GENERAL STATEMENT.

The general structural characters of the shell of the Ordovician and later brachiopods have been so fully described by authors that it does not appear to be necessary or desirable to repeat them. The student will find a full description given by Hall and Clarke in their "Introduction to the study of the Brachiopoda" [1892a, pp. 150-225].

Some of the more important works that contain data on the structure of the shell are those of Hancock,^a King,^b Carpenter,^c Davidson,^d and Mickwitz.^e

The greater proportion of the Cambrian brachiopods are largely corneous or chitinous. These are restricted to the inarticulates, but the inarticulates of the Cambrian do not all possess corneous shells. Mickwitz has shown [1896, pp. 102-142] that the shells of *Obolus* and its subgenera are essentially the same as those of *Lingula* in composition and structure. In both the shells are composed of successive calcareous and corneous lamellæ that vary in thickness and structure. The calcareous lamellæ are prismatic and crossed by minute tubules; the corneous lamellæ are compact and imperforate.

Hall and Clarke [1892a, p. 175], in speaking of the shells of the articulate brachiopods, say:

Among the articulate genera, under favorable preservation, there may be distinguished three distinct calcareous shell layers; an inner prismatic or fibrous layer, which constitutes the greater portion of the shell; above this is a thin lamellar layer, and the outer surface of the shell is covered by a tenuous epidermal film or periostracum. When the shell is punctate the tubules open on the inner surface in narrow apertures, whence they widen upward, abruptly expanding in the lamellar layer, at whose upper margin they terminate. They do not pierce the periostracum.

^a Hancock, A., On the organization of the Brachiopoda, 1859, pp. 791-869.

^b King, W., On some characters of *Lingula anatina*, 1873, pp. 1-17.

^c Carpenter, W. B., On the intimate structure of the shells of Brachiopoda, 1853, pp. 23-45.

^d Davidson, T., On the classification of the Brachiopoda, 1853, pp. 41-136.

^e Mickwitz, A., Ueber die Brachiopodengattung *Obolus*, 1896.

Among the calcareous, inarticulate brachiopods the shell of the Cambrian genus *Obolella* shows a dense, compact, slightly lamellated structure made up of a granular groundmass pierced by extremely small tubules or pores. The substance of the shells of *Rustella* and *Yorkia* is unknown, but from the character of the casts and the fact that the corneous shells of *Micromitra* in the same matrix are preserved it is probable that it was calcareous. The shells of *Quebecia*, *Trematobolus*, and *Dearbornia* are also calcareous.

In *Kutorgina* and *Schuchertina*, forms that may be referred to either articulate or inarticulate genera, the shells appear to be calcareous, compact, and without fibrous structure. Hall and Clarke, when speaking [1892a, p. 174] of the composition of the shell of the fossil linguloids, say:

In the group of fossil linguloids, beginning with *Lingula*, passing through *Lingulops* and *Lingulasma* to *Trimerella* and its allies, there is a regular increase in the relative amount of calcareous matter in the shell, so that the *Trimerellas*, which are large and ponderous shells, seem to have wholly lost their corneous matter.

The predominance of corneous or calcareous shell matter does not appear to be of more than generic importance in the classification of the brachiopods. It is true that the known articulate genera are all calcareous, but it is equally true that among the inarticulate group calcareous shells occur. Alteration, replacement, and removal of original shell substance have changed the shell of so many species that other characters must be depended on for classification.

MICROSCOPIC STRUCTURE.

In previous work on the Cambrian Brachiopoda, except in the cases above cited, practically no attention was paid to the microscopic shell structure. The importance of this feature in the classification of later species suggested the possible value of a microscopic study of the earlier forms, and at my request Mr. E. O. Ulrich and Mr. R. S. Bassler prepared thin sections and also assisted in the preparation of figures 1-15 (pp. 298 and 299) and in the preliminary study of the sections.

The preparation of thin sections of these early brachiopods is accompanied with difficulties which, together with the lack of sufficiently extensive collections, have undoubtedly prevented previous study along the same line. Specimens suitable for sectioning, especially of the calcareous forms, are not at all common, and when they do occur they are almost invariably buried in the rock and are so thin that the parting of the inclosing matrix does not leave sufficient shell substance for the preparation of sections. In the present work the specific identity of a shell was first determined by uncovering about one-half the valve, and the other half, still embedded in the matrix, was then used in making the section. The structural features are often restricted to individual lamellæ and the right zone for microscopic examination was determined simply by close observation as grinding proceeded. Both vertical and tangential sections were prepared, the former cutting the shell at right angles and the latter cutting the shell in planes more or less parallel to the layers or lamellæ of which it is composed. The most interesting results were obtained from the tangential sections, as the thin shells showed little decided structure in vertical sections.

Description of figures 1-15a.^a

Billingsella plicatella Walcott [1905a, p. 240]:

FIGURE 1.—Diagrammatic sketch of a small portion of a tangential section, $\times 200$. The granular groundmass, with small pores and tubules 4 or 5 times their own diameter distant from each other, is also typical of other members of the Billingsellidæ. Upper Cambrian, Gallatin Valley, Montana.

Dalmanella subequata (Conrad) [1843, p. 333]:

FIGURE 2.—Photograph of a tangential section, $\times 35$, showing the fibrous structure and comparatively large pores. Ordovician, St. Paul, Minnesota.

Kutorgina cingulata (Billings) [1861b, p. 8]:

FIGURE 3.—A small portion of the tangential section shown in fig. 8, $\times 200$. The minute structure of this and the following species is essentially the same as that shown in fig. 5, the only difference being the closer arrangement of the pores. Lower Cambrian, Swanton, Vermont.

Obolus apollinis Eichwald [1829, p. 274]:

FIGURE 4.—Small portion of tangential section, $\times 200$. The minutely porous granular structure is beautifully shown in this species, in which the pores are arranged more closely than in any other observed. Upper Cambrian, *Obolus* sandstone, Esthonia, Russia.

Billingsella coloradoensis (Shumard) [1860, p. 627]:

FIGURE 5.—Photograph of horizontal thin section enlarged fifty diameters. This shows the characteristic granular groundmass of the Cambrian Billingsellidæ. Upper Cambrian, Morgan Creek, Burnet County, Texas.

Nisusia festinata (Billings) [1861b, p. 10]:

FIGURE 6.—Photograph of horizontal thin section enlarged fifty diameters. This section shows a granular groundmass in which faint indications of small pores or tubules may be seen with a high power. Lower Cambrian, 2 miles east of Swanton, Vermont.

Eoorthis remnicha (N. H. Winchell) [1886, p. 317]:

FIGURE 7.—Photograph of horizontal thin section enlarged fifty diameters. This section shows the same type of groundmass as that illustrated by fig. 6. Upper Cambrian, Cold Creek Canyon, Burnet County, Texas.

Kutorgina cingulata (Billings) [1861b, p. 8]:

FIGURE 8.—Photograph of horizontal thin section showing granular shell substance. There are few slight indications of pores. Lower Cambrian, Swanton, Vermont.

Dalmanella multisepta (Meek) [1873, p. 112]:

FIGURE 9.—Horizontal thin section enlarged fifty diameters. This shows the fibrous structure of the shell penetrated by numerous fine tubules. Ordovician, Eden shale, Cincinnati, Ohio.

Dalmarella parva (de Verneuil) [1845, p. 188]:

FIGURE 10.—Horizontal thin section showing fibrous structure; also section of the tubules that penetrate through the shell. Middle Ordovician of Russia.

Syntrophia lateralis (Whitfield) [1886, p. 303]:

FIGURE 11.—Horizontal thin section enlarged fifty diameters, showing the arrangement of the pores in lines that radiate from the apex toward the margin. Lower Ordovician, Beekmantown, Fort Cassin, Vermont.

Plectrothis plicatella (Hall) [1847, p. 122]:

FIGURE 12.—Horizontal thin section enlarged fifty diameters. This section shows the fibrous structure so characteristic of the Ordovician orthoids. Ordovician "Lorraine shaly limestone," Cincinnati, Ohio.

Huenella abnormis (Walcott) [1905, p. 289]:

FIGURE 13.—Horizontal thin section enlarged fifty diameters. The pores in this genus are smaller than in *Syntrophia*, but their arrangement is essentially the same and shows the line effect characteristic of the Pentameracea. Upper Cambrian, Gallatin Valley, Montana.

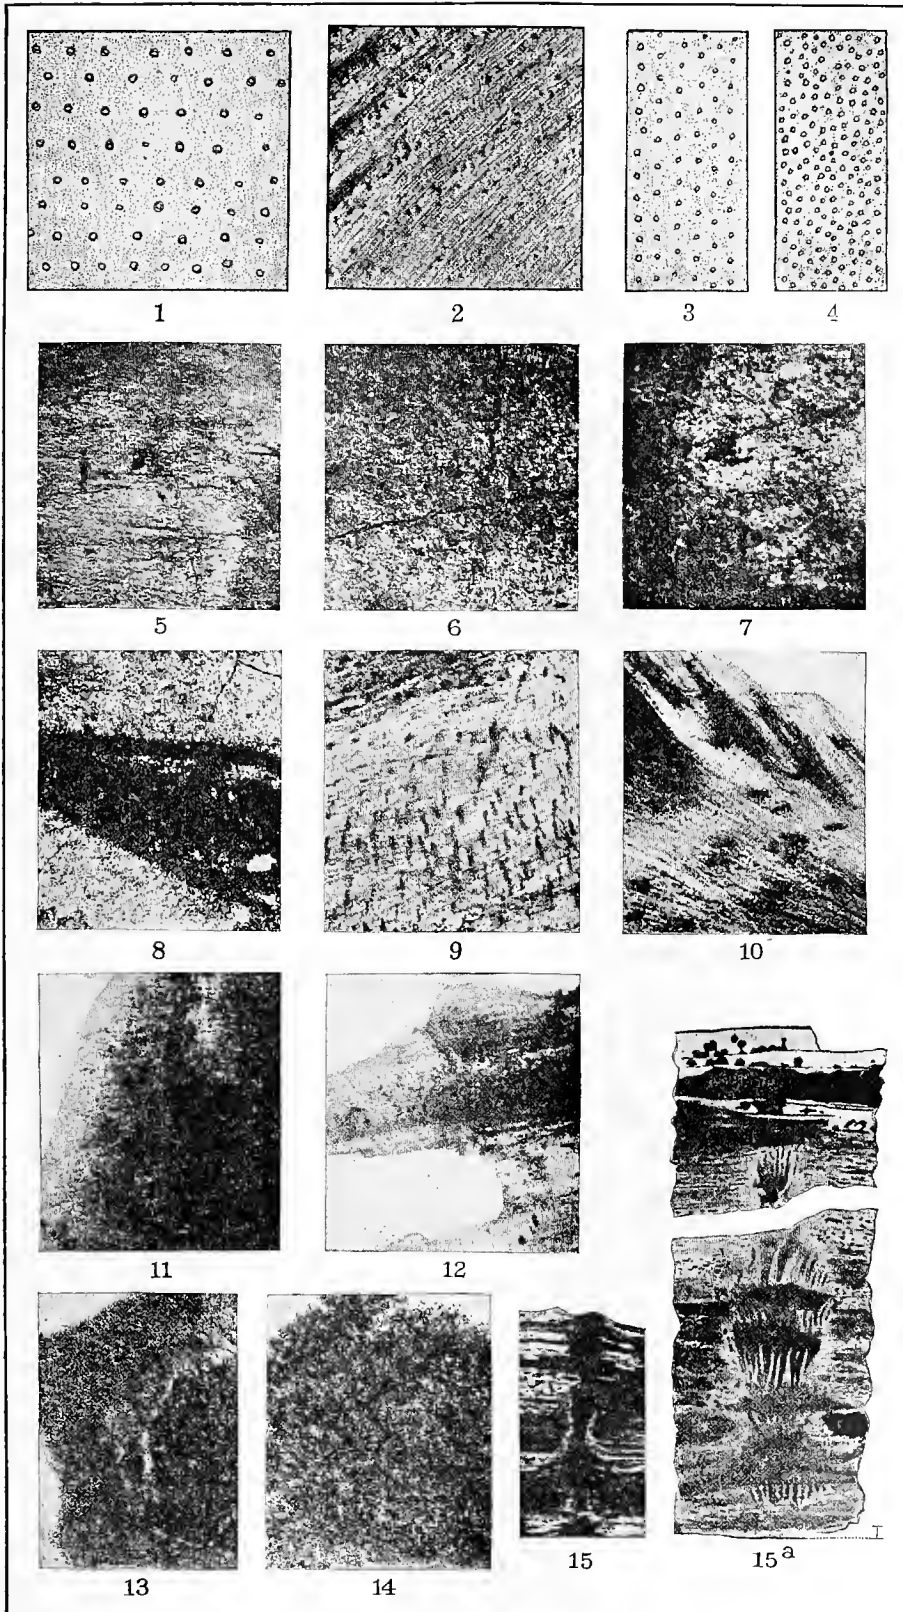

Obolella crassa (Hall) [1847, p. 290]:

FIGURE 14.—Horizontal thin section enlarged fifty diameters. This shows the fine granular groundmass, with an indication in the upper left side of the section that a surface ornamentation has been cut across. Lower Cambrian, Bic, Canada.

Obolus apollinis Eichwald [1829, p. 274]:

FIGURES 15 and 15a.—Transverse vertical thin sections enlarged so as to show the lamellæ and the presence of a large tubule that appears to have more or less imperfectly penetrated through the shell. Upper Cambrian, *Obolus* sandstone, Russia.

^a Figs. 1-4 are copied from figs. 2-5 on p. 151 of a preliminary paper on the classification of the Cambrian Brachiopoda [Walcott, 1908e]. Figs. 5-15 and 15a are copied from figs. 1-12, Pl. XII, of the same paper.

The general resemblance of the Cambrian eorthooids to certain Ordovician Protremata is so striking and the lines of descent so suggestive that particular attention was devoted to this group. Examination, however, brought out the fact that this apparent relationship disappears when the shell structure of the two groups is compared.

Sections of the shells of members of the Billingsellidæ, of which figure 1 is typical, all show a lamellar structure with indications of more or less numerous, scattered, very minute pores or tubules passing without interruption through one lamella. In some sections the spots indicating the tubules are arranged in rows radiating from the beak of the shell to the margins, but no other regular arrangement can be seen. The great mass of the shell is made up of a compact, finely granular base with dark spots and occasional minute crystals of calcite, a groundmass which, under the microscope, appears very much like that of a fine argillaceous shale.

The Ordovician Protremata have a clearer, more crystalline aspect or color than the Cambrian Billingsellidæ, a difference which probably indicates either a purer lime composition for the former or more probably a higher percentage of calcium phosphate for the latter. In chemical aspect the shells of the Billingsellidæ appear to resemble those of the Atremata and Neotremata more closely than do the Orthidæ. (Compare figs. 1, 3, and 4 with 2.)

Analyses of the respective shells would be necessary to prove these relations, but they are interesting subjects for investigation in view of the possible derivation of the Billingsellidæ from the Atremata.

In the Cambrian articulate genera, with the possible exception of *Syntrophia* and *Huenella*, the minute, fibrous structure so characteristic of most if not all orthoids is entirely absent. (Compare figs. 1 and 2.) *Syntrophia* and *Huenella*, however, greatly resemble each other. Thus sections of the shell of *Huenella abnormis* of the Upper Cambrian (fig. 13) and *Syntrophia lateralis* of the Lower Ordovician (fig. 11) show the same radial arrangement of the pores seen in the Billingsellidæ, but the shell structure is fibrous and the rows are coincident in direction with the fibers. On closer study this apparently fibrous structure can be resolved into more or less parallel bands or walls of shell substance separating rows of closely arranged, rectangular, porelike spaces. These spaces may be seen distinctly in thick sections, but they disappear when the section is made sufficiently thin to give a clear image under very high power. Sections of the linguloid genera were also prepared and studied, but the thinness of the shells and their phosphatic character prevented very satisfactory results. The irregular large tubules mentioned by Mickwitz [1896, p. 106] are beautifully shown in sections of *Obolus apollinis* before me.

Some of the tubules penetrate several lamellæ of the shell and suggest the tubules of some of the orthoids. (See figs. 15 and 15a.) The same general structure, with the exception of the larger tubules, appears to be characteristic of all of the corneous shells of the Atremata and Neotremata, and, so far as known to me, of all of the Cambrian corneous shells.

Figures 5-14 are from photographs which have not been retouched, so that personal equation may be eliminated. Unfortunately, higher magnifications could not be used without a loss of clearness, but even at the present magnification these views show decided differences in structure.

In conclusion, it appears that the Cambrian Billingsellidæ are further removed from the Ordovician and later Protremata than has hitherto been suspected, the microscopic shell structure in the former being of granular material pierced by small pores and in the latter of fibrous material. On the other hand, the microscopic structure of the Cambrian and later Pentameracea is so similar that an unbroken line of descent is indicated.

SURFACE ORNAMENTATION.

GENERAL STATEMENT.

The known protogulum of all brachiopods is smooth, and the shells have usually advanced well into the nepionic stage of growth before the outer surface is ornamented to any considerable degree. Many species of Cambrian inarticulate brachiopods (especially the Obolacea) remain smooth through all stages of growth, with the exception of lines and varices of growth. Many of them, however, have some form of ornamentation, and some of the most ornate types of surface,

such as that of *Micromitra* (*Iphidella*) *pannula* (Pl. IV) and *Botsfordia cælata* (Pl. LIX), were fully developed in Lower Cambrian time.

I have given much attention to the question of the value of surface ornamentation for the purposes of systematic classification among the Cambrian brachiopods, and have concluded that only in cases where a distinctive surface is persistent for a considerable period can it be considered of more than specific value. In one instance I have given the type of surface found on *Obolus* (*Westonia*) *aurora* (Pl. XLVI, fig. 1h) a subgeneric value, but its wide range of variation makes me doubtful of its utility.

ATREMATA.

So far as known, the outer surface of *Rustella*, the most primitive type of brachiopod known (Pl. I, figs. 1, 1a-e), is marked only by concentric growth lines. Among other genera referred to the Paterinidæ, *Volborthia* (Pl. I, figs. 6, 6a-e) has only concentric growth lines on the outer surface, although it has numerous radiating lines on the inner laminations of the shell. On the outer surface in the genera *Mickwitzia* (Pl. VI) and *Helmersenina* (Pl. LXIII, figs. 7, 7a, and 7e) are found concentric and radiating lines and small tubercles (apparently rudimentary spines) that are ornamental in their arrangement and effect, but it is in *Micromitra* that the greatest variety and most highly ornamented surfaces appear. Species that have a simple type of surface, marked only by concentric lines of growth, are grouped under the subgenus *Paterina* (Pl. II), while those having an ornate surface (Pl. IV) are included in the subgenus *Iphidella*. Transition forms, intermediate in surface ornamentation between the two extreme types, are referred to *Micromitra*, since the type species, *M. sculptilis*, has this intermediate form of surface. The species *Micromitra* (*Paterina*) *pealei* (Pl. III, figs. 3, 3a-e) approaches closely to *Micromitra sculptilis* (Pl. III, figs. 5, 5a, and 5e) but is not quite so highly ornamented. *Micromitra* (*Iphidella*) *pannula* and its varieties (Pl. IV) have a highly ornate surface, and the species has both wide geographic distribution and stratigraphic range. It is abundant in the Middle Cambrian and it also occurs in the upper portion of the Lower Cambrian section in Nevada. The oldest known brachiopod from British Columbia, *Micromitra* (*Iphidella*) *louise*, which occurs 3,090 feet down in the Lower Cambrian terrane, has an ornamented surface much like that of *M. (I.) nyssa* (Pl. III, fig. 9), which occurs at the summit of the Lower Cambrian in the same stratigraphic section.

None of the Obolidæ of the Lower Cambrian is known to have an ornamented surface, but in the Middle Cambrian many species show, in addition to the concentric striæ and lines of growth and the radiating striæ and ridges, a variously pitted and granulated surface primarily formed by the crossing of the radiating and concentric ridges by oblique undulating ridges.

What I have called the *Westonia* type of surface (Pls. XLVI and XLVII) is the most common. A variety of this type where the lines are transverse is more rarely seen (Pl. XLIX, fig. 1f and 1g). The *Westonia* surface is not confined to *Obolus* (*Westonia*), as it occurs among the Neotremata in the genera *Obolella* (*Glyptias*), *Botsfordia*, *Acrothele*, *Acrotreta*, and *Acrothyra*. (See description of *Obolus* (*Westonia*), p. 450.) It is also present on Ordovician and later brachiopods and it is known on *Lucinia divaricator* and other pelecypods. [See Winchell and Schuchert, 1895, pp. 345-346.]

In *Obolus* (*Acritis*) (Pl. XIII, fig. 3) the irregular, undulating, and more or less inosculating concentric ridges suggest one of the rudimentary characters of some types of the *Westonia* surface, but their origin was probably different. The surface of *Lingula cincta* Barrande [1879b, Pl. CV, figs. 1A, 2A, and 2f], from Étage E (Ordovician), is much like that of *Obolus* (*Acritis*) *anti-quissimus*, but it is probably an illustration of the persistence of a form of surface sculpture through several geologic formations and a corresponding period of time.

The surface of *Lingula eximia* Barrande [1879b, Pl. CV, block 1] is highly ornate. The figure is introduced on Plate XXXII, fig. 3, as a possible type that may be found to have existed in late Cambrian time. *Obolus* (*Mickwitzella*) *siluricus* (Pl. XV, figs. 1b and 1c) has fine crenulations on the front side of certain concentric ridges, a type of ornamentation that is unknown among the Cambrian brachiopods except in this one Upper Cambrian species.

The presence of spines in inarticulate genera is of rare occurrence. The oldest known indication of their presence in other families than the Paterinidæ is on *Bicia gemma* (Pl. L, fig. 1a) and *Nisusia festinata* (Pl. C, fig. 1) of the Lower Cambrian. The Middle Cambrian *Nisusia alberta* (Pl. C, fig. 3c) has a series of strong spines, and, in the Upper Cambrian, *Acrotreta spinosa* (Pl. LXXIX, figs. 4a, 4b, and 4g), *Schizambon* (Pl. LXXXIV, figs. 1d and 3a), and *Helmerseniania ladogensis* (Pl. LXIII, fig. 7e) appear to have had a spinose surface.

NEOTREMATA.

Obolella (Pls. LIV and LV) has, so far as known to me, only concentric lines and ridges of growth, but the surface of *Botsfordia* is usually quite ornate. The granular type is best shown by *B. granulata* (Pl. LVII, fig. 4r) and *B. cœlata* (Pl. LIX, figs. 1h and 1o), and the pitted or reticulated type, formed by the crossing of obliquely concentric ridges, by *B. pulchra* (Pl. LXII, figs. 5, 5a-f, and 5k). *Botsfordia? barrandei* (Pl. LVII, figs. 7, 7a, and 7b) appears to have a smooth surface or one marked only by concentric growth lines.

Trematobolus of the Siphonotretidæ is like *Obolella* in having a plain surface, but in *Yorkia orientalis* (Pl. LXXXII, fig. 3a) the surface is of the reticulated type and resembles that of *Micromitra (Iphidella) pannula* of the Atremata. *Siphonotreta* has a finely granulated surface (Pl. LXXXI, figs. 6 and 6a), also a pustulose surface (Pl. LXXXI, figs. 5 and 5a). The latter type is found in the Atremata in *Mickwitzia* (Pl. VI, fig. 2) and the granulated surface is present in *Botsfordia* (Pl. LVII, fig. 4r) of the Obolellidæ. The surface of *Schizambon* (Pl. LXXXIV, figs. 1d and 3a) differs from all other genera of the Neotremata except *Acrotreta* (Pl. LXXIX, fig. 4g) in being spinose.

The surface of *Acrothele* varies in almost the same manner as that of *Micromitra*. Species occur with only concentric growth lines, as in *Acrothele subsidua* (Pl. LX, figs. 1c, 1d, and 1i), or the same species may have a few radiating ridges (Pl. LX, figs. 1a, 1b, and 8). The radiating ridges may be characteristic of some forms of the adult shells of the species, as in *A. matthewi multicostata* (Pl. LXI, figs. 5, 5a-c). In addition to these, there may be an irregular more or less inosculating series of fine concentric ridges, as in *A. avia* (Pl. LXII, fig. 1j); a finely granular surface, as in *A. coriacea* (Pl. LVI, fig. 1g); a more distinctly and strongly granular surface, as in *A. (Redlichella) granulata* (Pl. LVI, fig. 2g) or *A. prima costata* (Pl. LXI, fig. 4d). A pitted surface is sometimes formed by the crossing of obliquely concentric narrow ridges, as in *A. bella-punctata* (Pl. LVII, fig. 3b).

Only a few species of *Acrotreta* have more than the smooth surface with concentric lines. I was greatly surprised when I found a shell showing a spinose surface, *A. spinosa* (Pl. LXXIX, figs. 4a, 4b, and 4g), and again when I found a reticulated surface, *A.? cancellata* (Pl. LXXIX, fig. 5a). Both species are from the fauna of the Cordilleran sea; *A. spinosa* developed in late Cambrian time and *A.? cancellata* in early Ordovician time. The closely related genus *Acrothyra* has a very fine *Westonia* type of surface (Pl. XLVII) that can be seen only with the aid of a strong lens.

PROTREMATA.

The ornamentation of the surface of the shells of Protremata is usually in the form of radiating striæ, lines, and ridges of varying size and number, with concentric lines and ridges of growth. The radiating striæ, lines, and incipient ridges or plications are usually first seen on the inner laminations of the shell, and often this occurs in species that do not show it on the outer surface of the shell. This is beautifully shown in the atrematous genera *Mickwitzia* (Pl. VI, figs. 1k and 1l), *Obolus* (Pl. VIII, figs. 1i and 2; Pl. X, figs. 2 and 2e), *Obolus (Westonia)* (Pl. XII, figs. 7 and 7c; Pl. XLVII, figs. 1a, 1g, and 1m), *Obolus (Lingulobolus)* (Pl. XVI, figs. 1, 1b, 2c, 2f, 2h, and 2i), *Lingulella* (Pl. XVII, fig. 1l; Pl. XXXI, figs. 6e and 6g; Pl. XXXVIII, figs. 2d and 2f), *Lingulella (Lingulepis)* (Pl. XLI, figs. 1a-c, 1f-h, and 1j-m), and *Dicellomus* (Pl. LII, figs. 2c and 2h; Pl. LIII, figs. 1b, 1c, 2, 2a, 4a, 4d, and 4e). In *Bicia gemma* (Pl. L) the radiating lines and ridges occur on both the interior and exterior surfaces, and there are also elongated tubercles that suggest fine spines. In *Kutorgina granulata* (Pl. V, figs. 5b and 5c)

they are strong on the inner surface and less marked on the outer surface. Other species of *Kutorgina* (Pl. V) have a smooth, or only concentrically lined, surface. *Schuchertina cambria* (Pl. LI, figs. 6, 6a-m) has a fine series of internal radiating striae and ridges, but the exterior surface is without them.

Among the Protremata the radiating ridges are present in most genera, although some species of a genus may not have them. In the Billingsellinae a few species with smooth shells occur (Pl. LXXXVII, figs. 1, 1a-e, 7, 7a, 5, and 5a), but the greater number have both interior and exterior radiating ridges (Pls. LXXXVII-XC). Among the Nisusiinae and Eoorthinae all the species show more or less of external radiating lines and ridges; sometimes the young shells are nearly smooth (Pl. XCVIII, figs. 1f, 2b, and 5), but this in most cases is at a very young stage of growth. The Syntrophidæ show variation from the smooth adult shells of *Syntrophia calcifera* (Pl. CIV, figs. 1, 1a-i) to the strongly costate shells of *Huenella texana* (Pl. CIII, fig. 1e). *Swantonina* (Pl. CIV, figs. 5 and 6) has numerous radiating costae.

INTERLOCKING PPLICATIONS.

Interlocking of the margins of the valves began as soon as plications or ribs first appeared on the shell. The wide variation in size and number in the same species (Pl. CIII, figs. 1, 1a-g) indicates that this character is, like that of surface ornamentation, of little more than specific value. In the description of the surface ornamentation of the Protremata (p. 302) reference is made to the order of appearance and the character of the ridges or plications among the Cambrian brachiopods.

CARDINAL AREA.

ATREMATA.

In the protogulum stage of the atrematous shells the posterior margins of the valve are not bent regularly inward toward each other and there are no indications on the surface of a cardinal area. There is a simple cleft, the length of which is dependent on the degree of rounding of the posterior margins. Among the genera and species referred to the order Atremata, the pseudodeltidium of *Rustella edsoni* (Pl. I, figs. 1b, 1c, 1e) is extremely rudimentary, if developed at all, and there is no trace of a thickened cardinal surface. The pedicle appears to have impressed itself on the shell to the extent of making a shallow furrow on the posterior inner margin of the rather thick shell of the two valves. In *Mickwitzia monilifera* (Pl. VI, fig. 1'') the pressure and movement of the pedicle against the vertical cardinal margin during the growth of the shell have had the effect of bulging it outward so as to produce a pseudodeltidium, but on neither of the valves is there a trace of a cardinal thickening. In *Helmersenina ladorgensis* (Pl. LXIII, fig. 7d) a pseudodeltidium similar to that in *Mickwitzia* occurs on the ventral valve, and here also there is only a thickening of the posterior margin and not a true cardinal area. In the genus *Micromitra* the mechanical influence of the pressure of the pedicle on the ventral valve is much more pronounced; in *Micromitra (Paterina) bella* (Pl. II, figs. 1a and 1b) the pseudodeltidium is more clearly defined than in *Mickwitzia* or *Helmersenina*, and the concave arch of the cardinal margin for the protrusion of the pedicle is greater. In *Micromitra (Paterina) superba* (Pl. II, fig. 7) the excavation of the pseudodeltidium has increased, and in *Micromitra (Paterina) logani* (Pl. II, fig. 6b) and *Micromitra (Iphidella) pannula* (Pl. IV, figs. 1d, 2a'', and 2b') the pseudodeltidium has been excavated to such an extent that there is nearly an open delthyrium. This difference in delthyrial openings must be due to variation in the thickness of the pedicle. Attention is called to the pseudodeltidium shown in figure 2a'', Plate IV, where the tripartite, longitudinal division recalls the pseudodeltidium of *Acrotreta nicholsoni* (Pl. LXXIII, figs. 1g and 1h). So far as known to me, no true cardinal area is present in any species of the Paterinidæ, though there may be a more or less marked thickening or bulging of the posterior margin of the valves to form a pseudodeltidium.

In the Obolidæ the vertical cardinal area is present in all known species, but in varying degree of development. It is slightly shown in *Delgadella* (Pl. XXIX, figs. 5, 5a, and 5b) and well defined in *Obolus prindlei* (Pl. XXVII, figs. 3a, 3b, 3c, and 3e), *Lingulella granvillensis*

(Pl. XXII, figs. 1 and 1b), *Lingulella nathorsti* (Pl. XXXI, figs. 1 and 1a), and *Lingulella schucherti* (Pl. XXI, fig. 6), all of which are from the Lower Cambrian. *Lingulella schucherti* is probably the oldest known species, unless it be *Delgadella lusitavica*. In *Dicellomus* the cardinal area of the ventral valve (Pl. LII, figs. 1c and 1d) is not unlike that of *Obolus*, except that short teeth (Pl. LII, fig. 1d) appear to have been developed, and that on the cardinal area of the dorsal valve (Pl. LII, fig. 1i) there is a socket-like groove on each side for the reception of the projection in the ventral valve. On other specimens of the area of the dorsal valve there are many minor depressions or crenulations (Pl. LII, fig. 1j), but no defined groove or socket. On the dorsal valve of another species the cardinal area (Pl. LIII, fig. 1) is not unlike that of the dorsal valve of *Obolus*. There is considerable variation in the details of form and size of the vertical cardinal areas of the various species of *Obolus*, its subgenera, and *Lingulella*, but it is all within the typical *Obolus*-like cardinal area as seen in *Obolus apollinis* (Pl. VII). A curious individual development or extension of the area is shown in some specimens of *Obolus namouna* (Pl. VIII, fig. 2a) and *O. rhea* (Pl. IX, fig. 1), where the posterior margin of the mantle appears to have been drawn farther forward inwardly and a thin deposit of shell made, so as to carry the front margin of the cardinal area far in advance of its usual position in the species of the genus. On *Bicia*, one of the oldest genera (Pl. L), the area is as strongly defined as it is in *Obolus* and its subgenera, and teeth or articulate processes are suggested. In *Elkanvia* (Pl. LI, figs. 1 and 1a) the cardinal area so merges into the thickened platform that it is not readily separable from it. I have referred to this as the internal cardinal area, or the area that is inclined inward from the plane of the margins of the valves and united by shell deposit to the interior of the shell. In *Neobolus* the internal cardinal area of the dorsal valve extends forward as a semicircular shelf (Pl. I, fig. 4b). It is a modified cardinal area on the plane of the margins of the valves, but in the adult it does not extend over the rounded posterior margin of the valve. The area of the ventral valve is unknown, but from the presence of an open delthyrium (Pl. I, fig. 4') it is not probable that a well-defined cardinal area exists.

In the dorsal valve of *Lingulella granvillensis* (Pl. XXII, fig. 1d), *Lingulella helena* (Pl. XXIV, fig. 3c), *Obolus* (*Westonia*) *euglyphus* (Pl. XLVIII, fig. 1e) there is a strong undercut or opening beneath the area adjoining the pedicle furrow. This also occurs in the ventral valve of the last-mentioned species (Pl. XLVIII, figs. 1c and 1d) and in many species of *Obolus* and its subgenera and in *Lingulella*. In other species the area may be thickened so as practically to close up the space between it and the inside of the valve (Pl. VII).

In *Kutorgina* (Pl. V) the cardinal areas are in a very rudimentary condition, and comparable with the rudimentary cardinal areas of *Micromitra* (Pls. II, III, and IV). The general form and structure of *Kutorgina*, taken in connection with the rudimentary cardinal areas beneath the beaks of the valve, give the areas a significance that those of *Micromitra* do not possess. It is highly probable that a number of intermediate forms, in which the cardinal areas gradually obtained their more mature character, were developed between the type from which *Kutorgina* was derived and *Nisusia* and *Billingsella*, but nothing is known of such intermediate forms in the Lower Cambrian. *Schuchertina* (Pl. LI, figs. 6, 6a-m) appears to have been descendant from some atrematous type that may also have been the ancestral stock of *Kutorgina* and the forms that passed into *Nisusia* and *Billingsella*. *Schuchertina* is a primitive protrematous genus still preserving strong atrematous characters—or vice versa, according to one's point of view.

NEOTREMATA.

The cardinal areas of the valves of *Obolella* (Pls. LIV and LV) of the Lower Cambrian are essentially the same in appearance as those of *Obolus*, except that they are not usually so strongly developed. They may also be compared with the cardinal areas of *Bicia* (Pl. L), especially the projections on the inner angle adjoining the pedicle furrow. The narrow, thickened cardinal margin in the ventral valve of *Obolella* does not clearly show from the interior view, although such specimens as that illustrated on Plate LIV, figure 2h, indicate that the area is not so prominent as in the ancestral form. This is more clearly shown on Plate LIV, figure 2g. In

Botsfordia cælata (Pl. LIX, figs. 1e, 1f, and 1k) the cardinal areas are present but subordinate as compared with the areas of *Obolella*. They are still less in evidence in *Botsfordia granulata* (Pl. LVII, figs. 4g-m) and *Botsfordia pulchra* (Pl. LXII, figs. 5g-j). In *Ncobolus* (Pl. LXXXI, figs. 2e-h) the reduction of the cardinal areas has progressed until they are no longer a marked feature of either valve. In *Trematobolus* (Pl. LXXXIII and Pl. LXXXIV, figs. 5a and 5b) the development of the pedicle tube is much more advanced than in *Obolella*, but the cardinal areas are here again a prominent feature; they are less clearly defined in *Yorkia* (Pl. LXXXII, figs. 1e-h), in which the pseudodeltidium of the ventral valve is developed (Pl. LXXXII, figs. 1b-c). In other forms of the Siphonotretidæ the cardinal areas as developed in the Obolidæ are not seen in the adult stages of growth.

It is interesting to note that the vertical thickened cardinal area is present in the oldest known brachiopod, *Trematobolus excelsis* (Pl. LXXXII, fig. 8), which occurs stratigraphically lower down in the Lower Cambrian of North America than any other species of brachiopod known to me. *Linnarssonella*, with its low false area and strongly marked interior of its valves, has also a well-defined cardinal area in some species (*L. modesta*, Pl. LXXVIII, fig. 5e; *L. girtyi*, Pl. LXXIX, figs. 1l, 1m, and 1r), in this feature suggesting that it is more primitive than either *Acrotreta* or *Acrothele*. *Quebecia* is a very ancient form, but so far as known it passed in the adult beyond the stage of having a vertical cardinal area. Nothing is known of the interior of *Discinolepis* of the Middle Cambrian, but in the dorsal valve of *Keyserlingia* the thickened cardinal area is a well-developed feature (Pl. LXXXI, fig. 4e). *Acrotreta* occasionally shows a vertical cardinal area in the dorsal valve (*A. definita*, Pl. LXIV, fig. 2d; *A. kutorgai*, Pl. LXV, figs. 3h-j; *A. curvata*, Pl. LXVIII, figs. 1k and 1l; *A. ophirensis*, Pl. LXXIV, fig. 1f; *A. ophirensis descendens*, Pl. LXXVIII, fig. 1c; and *A. marjumentensis*, Pl. LXXVIII, fig. 2c). Other examples doubtless occur, but it appears that in both *Acrotreta* and *Acrothyra* the vertical cardinal areas are absent or so reduced as no longer to be a generic character; the same is to an even greater degree true of *Acrothele*. *Acrothele bellula* (Pl. LVIII, figs. 5c-h) has a defined cardinal area in the dorsal valve and a trace of one on the ventral valve; otherwise, only the false external area back of the pedicle opening is known to me among the species of *Acrothele*, its subgenus *Redlichella*, or *Schizopholis*. Nothing is known of a thickened vertical cardinal area in *Orbiculoidea* or *Philhedra*.

PROTREMATA.

Two of the earliest forms of the Protremata (*Billingsella* (Pl. LXXXV) and *Nisusia* (Pl. C)) both have a clearly defined cardinal area on the ventral valve, divided by a delthyrium that is more or less completely covered by a deltidium. These characters appear to be developed in the same manner as in the Inarticulata; in other words, they are the result of holoperipheral growth and pedicle pressure bulging the median region of the cardinal area. No deltidial plates are known in the Billingsellidæ. So far as known *Otusia* has an open delthyrium. The cardinal area of *Wynnina* (Pl. LXXXIX, fig. 4b) has a large, open delthyrium, with no trace of a deltidium in any of the four specimens from India. The figure shows a bit of shell at the top of the delthyrium, but this is not in place. The identification of the subfamily Rafinesquinæ by *Eostrophomena* is of doubtful value (Pl. XCV, figs. 6, 6a-b) and nothing is known of the area of the ventral valve. *Eoorthis* (Pl. XCI), *Orusia* (Pl. XCVIII), and *Finkelburgia* (Pl. XCIII) have an open delthyrium in the ventral valve. The cardinal area of *Swantonina* (Pl. CIV, figs. 5 and 6) is unknown. *Hucnella* has a clearly defined area on both valves and an open delthyrium (Pl. CIII, figs. 1c, 2g, 2i, and 3'').

DELTHYRIUM AND DELTIDIUM.

The development of the delthyrium from the simple *Rustella* stage, where it is scarcely more than a broad opening between the valves, to the definite form in the higher types of the Protremata, where it is either open or more or less closed by a deltidium, has been outlined in

connection with the notes on the cardinal areas. The evolution in the Atremata, Neotremata, and Protremata has been in the same direction, ranging from the open-fissured protegulum stage in pre-Cambrian time to the fully developed, clearly defined, subtriangular, usually convex pseudodelthyrium and deltidium. In *Acrotreta kutorgai* the cardinal area and deltidium of the dorsal valve are well defined (Pl. LXV, figs. 3i and 3j). I am inclined to think that the pseudodeltidia of the Atremata and Neotremata, as also the deltidia of the Protremata of the Cambrian, are all the result of holoperipheral growth and not of growth from a prodeltidial plate, as interpreted by Beecher [1892, p. 142].

The deltidia of the Protremata vary in size from the large deltidium of *Billingsella coloradoensis* (Pl. LXXXV, figs. 1n and 1o) to those in which the delthyrium is entirely open in the mature stages of the individual. The exact stage at which the rudimentary deltidia resulting from the holoperipheral growth of the shell begin to take on the more definite form shown in *Nisusia* (Pl. C) and *Billingsella* (Pl. LXXXV) is unknown.

From my studies of the Cambrian brachiopods I see nothing that leads me to the belief that in the Protremata the deltidium has a different origin from the pseudodeltidium of the Atremata. Whatever the significance of the prodeltidium or third shell plate of the Neotremata may be, it is plain from the many species of Atremata, Neotremata, and Protremata throughout the Cambrian that the pedicle openings tend to develop in two directions; resulting, first, in a more or less large open delthyrium, due in all probability to a thick and short peduncle filling up the space, and, second, in a more or less covered delthyrium (the covering being either the phosphatic pseudodeltidium or the calcareous deltidium), the peduncular opening being either between the two valves or reduced to a foramen limited to the ventral valve.

LISTRUM.

Hall and Clarke [1892a, p. 153] deemed it important to apply the term listrium to the calcareous deposition or plate closing the progressive track of the pedicle opening or pedicle cleft posterior to the apex of the ventral valve. This feature is known only in *Orbiculoidea* among Cambrian genera of Brachiopoda. It has not been observed in the Siphonotretidæ.

PSEUDOCHILIDIUM.

The pseudochilidium is a convex plate closing the primitive aperture in the dorsal valve of Atremata and Protremata. It corresponds to the pseudodeltidium of the ventral valve and is formed about the dorsal side of the pedicle aperture.

CARDINAL PROCESS.

The cardinal process, like the crura, was evidently developed in the interval of progression represented between the progenitor of *Kutorgina* and *Billingsella*. The process is unknown in *Kutorgina*, but is very clearly developed in the Middle Cambrian forms of *Billingsella* (Pl. LXXXV, figs. 1u-y; Pl. LXXXVI, figs. 3l and 3n; and Pl. LXXXVIII, figs. 1f and 1i). I have not observed it in *Nisusia* or *Nisusia* (*Jamesella*) of the Lower and Middle Cambrian. It appears in *Eoorthis remnicha* (Pl. XCI, figs. 1q and 1r; Pl. XCII, fig. 2b) of the Middle Cambrian, but I have not seen it distinctly in the Ordovician *Protorthis* (Pl. XCIX).

The development of the process followed the definite cardinal area and hinge teeth and must at first have been quite rudimentary. Its absence in *Nisusia* and its presence in *Billingsella* indicate that the latter is a more progressive type in this respect. In the Middle Ordovician orthoid *Dinorthis subquadrata* the cardinal process is striated and fluted so as to give a better holding surface for the attachment of the muscles. In the Silurian genera *Waldheimia* and *Cliothis* the entire concave part of the area of the dorsal valve projects as a plate posteriorly beyond the beak.

The cardinal process becomes more specialized in its bifurcated condition in the Strophomenidæ and Productidæ, etc. (See Hall and Clarke [1892a, p. 168] for further description of this process.)

ARTICULATING PROCESSES.

Among the Atremata, *Bicia* of the Lower Cambrian shows strong projections on the anterior portion of the cardinal area of the ventral valve beside the delthyrium (Pl. L, figs. 1i-k and 2a), but no corresponding sockets or means of articulation in the dorsal valve. It is a matter of interest to note that bosses occur on both valves (Pl. L, figs. 2, 2a-e) close to the front margin of the cardinal area, which were evidently of service in connection with the movement of the valves. In *Dicellomus* the area of the dorsal valve is sometimes grooved in such a manner (Pl. LII, fig. 1i) as to suggest an articulation with a projection on the ventral valve, and the crenulated margin of figure 1j is suggestive of another tendency toward developing articulation of the valves.

The actual presence or absence of articulating processes in *Kutorgina cingulata* (Pl. V) is very difficult to demonstrate by observation, owing to the character of the matrix in which the specimens occur. That some form of articulating processes is present, however, is indicated by the facts (1) that in a relatively small collection thirty of the valves are united, and (2) that in only a few instances is the dorsal valve in any other than the normal position in which it would have been held by teeth in the ventral valve. In only a few of the specimens have the valves slid or turned either way, as they usually do in the inarticulates.

In the Neotremata, the Lower Cambrian *Obolella* (Pl. LV, figs. 1e-g) has projections suggesting an articulating process on either side of the delthyrium. The same is true of *Trematobolus* (Pls. LXXXIII and LXXXIV).

In the Protremata the articulating processes are well developed in *Billingsella* (Pl. LXXXV, figs. 1n, 1v, and 1w), and, so far as known, in *Nisusia* and the other genera of the order.

SPONDYLIIUM.

I am inclined to agree with Doctor Schuchert that the spondylium originated as the result of deposition, within the ventral rostral cavity, of testaceous matter about the bases of the adductor, diductor, and pedicle muscles [Schuchert, 1897, pp. 100-102]. With this conception in mind we may consider that the slightly demarked rostral muscular area of *Nisusia* is one of the earliest known traces of pseudospondylia, and that it is followed by the more decidedly elevated muscular area or pseudospondylium of *Billingsella*, which is of the same type as that of *Clitambonites* and essentially of the same general type as that of *Eoorthis*. In *Filkeburgia* the pseudospondylium appears to have been supported at its anterior margin by three septa (Pl. XCIII, fig. 2), thus forming a link between the pseudospondylium of *Billingsella* and the spondylium of *Syntrophia*. In *Huenella* (Pl. CIII, figs. 1h, 1i, 2l, and 2m) the spondylium is free at the sides and without a supporting septum (as in *Syntrophia*, Pl. CII, fig. 6g; Pl. CIII, figs. 4d and 4e) or septa (as in *Clarkella*, Pl. CIV, figs. 2c and 2d).

Protorthis has no well-observed cardinal process in the dorsal valve, although it has gained a true spondylium in the ventral; and *Syntrophia* gains a cruralium in the dorsal valve, both valves of *Syntrophia rotundata* having either a spondylium or cruralium supported on a median septum (Pl. CIII, figs. 4d and 4e). In *Clarkella* the spondylium is supported by three or more septa (Pl. CIV, figs. 2c and 2d).

In chronologic order the pseudospondylium of the ventral valve first appears in the Lower Cambrian *Billingsella highlandensis* (Pl. LXXXVII, fig. 4b) and *B. orientalis* (Pl. LXXXVI, fig. 2). It is present in all species of *Billingsella* from the Middle and Upper Cambrian, and has the same form in the Middle Cambrian as in species of *Eoorthis* of the Middle and Upper Cambrian. On this line of descent the pseudospondylium appears in *Orthis* (see Hall and Clarke [1892c, pp. 186-194]) of the Ordovician and later faunas, probably as a reversion from a free spondylium. On the line of descent to *Protorthis* the pseudospondylium becomes a free spondylium and continues on through *Syntrophia* and *Clarkella* into the Ordovician and Silurian Pentameridæ and Clitambonitidæ.

It is not improbable that all Cambrian and Lower Ordovician Protremata have a pseudospondylium or spondylium. In the Orthidæ a pseudospondylium is often suggested, but the

dental plates do not appear to join to form an attached (pseudo) or free spondylium. The points of attachment of the adductor (central) muscle scars appear to have been directly on the surface of the valve and not on a raised platform or pseudospondylium.

At my request, and with all the illustrations of this monograph for study, E. O. Ulrich, who has been studying the Ordovician Protremata, prepared the following notes on the spondylia of the Cambrian and Ordovician Protremata:

Spondylium. This structure, if we regard the term spondylium as referring only to the typical free or medially supported umbonal camera or spoon, is of more common occurrence among articulate brachiopods than is usually believed. Hall and Clarke [1892a, pp. 328-335] discuss the theoretic relations of the spondylium to the deltidium and suggest an expansion of the former term that seems to me to be disproved by the chronogenesis of the articulate brachiopods.

The typical spondylium is more or less rhomboidal in outline and corresponds to a ventral muscular area which is raised above the floor of the valve and formed by the convergence and union of the dental plates. To the concave surface of this structure the ends of the adductor, diductor, and pedicle muscles are attached.

The manner in which the spondylium is attached to the bottom of the valve is so variable that the feature does not seem to be of more than generic consequence. It is free in *Protorthis* and in a related new Ordovician genus; supported by one or three septa in *Clitambonites*, *Pentamerus*, *Syntrophia* (s. s.), *Clarkella*, etc.; partly sessile but anteriorly supported by one or three septa in *Finkelnburgia*; and wholly sessile (resting entirely on the bottom of the valve) in *Otusia* and *Orusia*, *Eorthis*, *Billingsella*, *Huenella*, and certain *Clitambonitidae*, *Syntrophiidae*, and *Pentameridae*. The muscular area of the ventral valve of the Cambrian *Orthis*-like brachiopods never agrees perfectly with that of any of the described Ordovician *Orthidae*. In the latter the dental plates of the ventral valve never meet and the area is more or less distinctly bilobed and very rarely elevated, though it may be so depressed in thick shells as to suggest a spondylium. In the Cambrian types in question the muscular area is often elevated, commonly suggests and frequently forms a true spondylium, and as a rule is more or less distinctly rhomboidal in outline. These features, together with the arrangement and components of the muscle scars of the dorsal valve, suggest a relationship with the Ordovician *Clitambonitidae* rather than with the true *Orthidae*.^a

Of the true Ordovician orthoids, it seems to me that the groups represented by *O. callactis-tricenaria* and *Dalmanella* (especially the *D. subaquata* section) are the oldest and most persistent. Both of these types often retain unresorbed remnants of the deltidium, and in the development of their dental plates and septa and in the shape and arrangement of their ventral muscular areas they agree with the average Cambrian articulate more closely than do any other Ordovician or Silurian orthoids, with the possible exception of *Plectorthis*. Thus, except in the matter of surface plication, the resemblance between *Orthis tricenaria* and *Billingsella romingeri* (Barrande) is rather striking. But it is to be noted that the muscular area in the ventral valve of *O. tricenaria* (as in *Dalmanella subaquata*) is blunt and gently bilobed or obscurely trilobed anteriorly, and not subrhomboidal in outline. *Plectorthis whitfieldi* has longer and broader ventral adductor scars than any other Ordovician or Silurian orthoid known to me, and on this account its muscular area resembles that of *Billingsella* more closely. *Plectorthis whitfieldi* is, however, of late Ordovician or Silurian age and lived at a time of very rapid evolution (and possibly reversion) among brachiopods, when other orthoids of the same type (*Orthis* (*Billingsella*) *laurentina* (Billings) and *Orthis flabellites*) were reverting to ancestral characters; or it may be that they were immigrants from some other area where the older characters persisted.

This difference in shape of the ventral muscular area in the *Billingsellidae* and *Orthidae* is due to the fact that in the former the median (adductor) scars are always longer and as wide or wider than the lateral (diductor) pair. In the *Orthidae* the adductor scars are of the same general shape as the corresponding scars in the *Billingsellidae*, but are relatively smaller and shorter. They are as long as the diductors in *Orthis tricenaria*, *Plectorthis whitfieldi*, and *Dalmanella subaquata*, and in others [*Dinorthis*, *Rhipidomella*, etc.] they are much shorter and more or less completely inclosed anteriorly by the revolutionary tendency of the area of the diductors to expand at the expense of the adductors.

A natural division of the orthoids into two families may thus be established:

(1) Ventral muscular area small, obovate or obcordate; adductors reaching front margin of area (*Orthis* (s. s.), *Plectorthis*, *Platystrophia*, *Hebertella*, *Orthostrophia*, *Dalmanella*).

(2) Ventral muscular area large, bilobed or elliptical; adductors proportionately small and more or less completely inclosed anteriorly by the flabellate diductors [*Heterorthis*, *Plasiomys? deflecta* group, *Dinorthis*, *Bilobites*, *Rhipidomella*, *Schizophoria*, *Orthotichia*].

Another well-marked difference between the true Ordovician orthoids and their *billingsellid* ancestors is in the arrangement of the muscle scars of the dorsal valve. In the *Billingsellidae* they are somewhat elongate and more or less radially arranged (Pl. LXXXVIII, figs. 1f-k; Pl. XCIII, fig. 1f; and Pl. XCIX, fig. 2d) and in the *Orthidae* [*Orthis tricenaria*, *Plectorthis*, *Dalmanella*, and *Orthis tritonia*] they are shorter and placed longitudinally. Some of the later orthoid forms in the second group [*Bilobites*, *Rhipidomella*, and *Schizophoria*] are characterized by a radial arrangement of the dorsal muscle scars, but the ventral muscular areas are here highly developed and bear little resemblance to those of the *Billingsellidae*.

^a Commenting on this, Dr. Charles Schuchert wrote me: "This is a very important point. It has often struck me that all the early Cambrian brachiopods have an incipient spondylium, sometimes free, sometimes supported, or sessile. Out of the sessile forms have developed the true orthoids."

CRURALIUM.

In the dorsal valve an immature cruralium is seen for the first time in *Nisusia festinata* (Pl. C, fig. 1g at d, and fig. 1j at cr) which is without a cardinal process; this appears to be the first appearance in the Lower Cambrian of a muscle-supporting projection in the dorsal valve of an articulate brachiopod. In *Billingsella* a cardinal process is developed (Pl. LXXXV, figs. 1u and 1v) on a low crural thickening. This process is present in *Eoorthis* and *Orthis* and is prominent in *Dinorthis*, *Hebertella*, and most of the Orthidæ, Strophomenidæ, and Productidæ.

A well-developed cruralium in the dorsal valve is first seen in *Syntrophia* (*S. rotundata*, Pl. CIII, fig. 4e) of the Upper Cambrian. It is well developed in *Clarkella*, *Conchidium*, and other genera of the Pentameracea.

PLATFORM.

Hall and Clarke [1892c, p. 46]^a state that—

The specialized postmedian testaceous deposit which has been termed the platform by Messrs. Davidson and King occurs among Brachiopoda only in the genera *Lakhmina* [= *Neobolus*], *Lingulops*, *Lingulasma*, *Dinobolus*, *Trimerella*, *Monomerella*, and *Rhinobolus*; it constitutes the principal diagnostic character of the family Trimerellidæ of those authors, and in so far as any of these genera possesses this feature, so far, at least, it is a trimerellid. In its thronogenesis it is accompanied by certain peculiar phenomena. According to our present knowledge, its first appearance is in the little *Lakhmina* [= *Neobolus*] from the primordial "Obolus beds" in the Salt Range of India; but in American faunas, where the development of the group is best exemplified, it is first met in *Dinobolus* (in external features the most oboloid form of the group) in the later faunas of the Lower Silurian: Black River, Trenton, Galena. Thereupon follow in the still later fauna of the Hudson group the more pronounced linguloid genera, *Lingulops* and *Lingulasma*. Not, however, until the introduction of the Niagara or Wenlock fauna does the entire group, with the exclusion of the inceptive linguloid forms, reach its culmination in specific and individual development. * * * With the disappearance of this fauna the platform-bearing brachiopods virtually became extinct, and we have as yet no trace whatever of the occurrence of this peculiar feature at any later date or in any other group of these animals.

These authors conclude that it is probable—

that the inception of the platform is due to the slight variation indicated in the mode or rate of formation of the muscular fulcra in *Lingula*, and this may itself have been due in part to a simple increase in the size of the muscular bands.

In summing up their conclusions on the source and development of the platform in the trimerellids, the statement is made that "we are confronted with the interesting phenomena of a similar resultant attained along different lines of development." This is expressed in a diagram in which *Obolella* and *Lingulella* are taken as the first stages of two lines of development. On the line of *Obolella* come in succession *Obolus*, *Elkania*, *Dinobolus*, and *Trimerella*. On the line of *Lingulella* come in succession *Lingula*, *Lingulops*, *Lingulasma*, *Trimerella*, and, as an offshoot from *Lingulasma*, *Monomerella* and *Rhinobolus*. *Lakhmina* [= *Neobolus*] is placed in a central line between *Obolus* and *Lingulella* [Hall and Clarke, 1892c, p. 52]. For the full discussion of the views of Hall and Clarke the student should consult the original work [Hall and Clarke, 1892c, pp. 46-55].

In the course of my studies of the Cambrian brachiopods I came to the conclusion that the platforms so far as developed were the result of shell secretion beneath and about the points of attachment of the muscles, also beneath the visceral cavity. In the dorsal valve of *Rustella* (Pl. I, fig. 1e) from the Lower Cambrian, the most primitive type of brachiopod known to me, the central and anterolateral muscle scars are slightly raised above the general level of the interior of the valve; many natural casts of the interior of the ventral valve fail to show traces of the points of attachment of the muscles.

I have assumed that *Obolus* was divergent from the same stock or radicle as *Rustella*, and that *Lingulella* is an early divergent from *Obolus*. (See schematic diagram, p. 317.) None of the Lower Cambrian species of *Obolus* or *Lingulella* known to me has any unusual thickening of the valves over the visceral area or about the muscle scars, but in the Middle and Upper Cambrian it is not uncommon to find more or less indication of it. *Obolus mickwitzii* (Pl. X, figs. 1, 1a-k) of the Middle Cambrian is a striking example, and *Obolus apollinis* (Pl. VII) of

^a Observations on the development and function of the platform in the inarticulate Brachiopoda.

the Upper Cambrian affords fine illustrations of the general thickening of the shell beneath the visceral area in both valves, while the points of attachment of the muscles may be depressed (Pl. VII, figs. 10 and 17) or elevated (Pl. VII, figs. 9 and 14). The thickening of the shell is also well shown by the ventral valves of *Obolus* (*Schmidtia*) (Pl. XIV, figs. 1a, 3a, and 4a) and less well by the dorsal valves (Pl. XIV, figs. 1c, 4c, and 4d). *Obolus cyane* (Pl. XXVII, fig. 4b) from the Lower Ordovician has an unusually well-developed thickening beneath the visceral area of the dorsal valve. Many other illustrations might be given from *Obolus* and its subgenera.

In *Lingulella* and its subgenera there is a striking development of the primitive or early stages of the platforms, and they are present in many species—*L. acutangula* (Pl. XVII) and *L. granvillensis* (Pl. XXII, figs. 1b and 1d) of the Lower Cambrian and *L. dubia* (Pl. XXIV, figs. 4 and 4a) and *L. ino* (Pl. XXVI, fig. 4) of the Middle Cambrian. Of Upper Cambrian species only the small *L. ferruginea* shows a slight thickening of the valves beneath the visceral area (Pl. XXIX, figs. 1r and 1s).

From *Lingulella* there appears to have been an offshoot in Middle Cambrian time in *Obolus* (*Fordinia*) *perfectus* (Pl. LXIII, figs. 10, 10a–d) that developed a strong tendency toward the formation of a rudimentary posterior thickening in the interior of the valves. Two species, *Obolus* (*Fordinia*) *bellulus* (Pl. LI, figs. 3, 3a–f) and *O. (F.) gilberti* (Pl. LI, figs. 5, 5a–d) from the Upper Cambrian, also show the same tendency. The rudimentary platform of *O. (Fordinia) perfectus* (Pl. LXIII, figs. 10a and 10c) is intermediate in development between those of *Obolus apollinis* (Pl. VII) and *Elkania desiderata* (Pl. LI). The position of the central group of muscle scars, at the anterior sloping ends of elevated ridges, marking the path of advance of the scars with the growth of the shell, is beautifully shown in figure 10a of the ventral valve of *O. (F.) perfectus* (Pl. LXIII). In the dorsal valve of the latter species there is marked thickening of the shell beneath the visceral area, and a marked median septum or ridge just in front of the cardinal area (Pl. LXIII, fig. 10c) is very suggestive of a cardinal process. The ventral valve of *Elkania desiderata* (Pl. LI, fig. 1) has a strong, solid, rudimentary platform into which the interior cardinal area is blended, and the position of the central group of muscle scars is on the front slope of the platform; in the dorsal valve (Pl. LI, figs. 1c and 1d) a rudimentary platform is also clearly indicated. The dorsal valve of *Elkania ambigua* (Pl. LI, fig. 2c) may have a fairly strong rudimentary platform or be without it (Pl. LI, fig. 2b). *Elkania ida* (Pl. LI, figs. 4b and 4c) has the rudimentary platform finely developed in both valves.

Lingulasma schucherti [Hall and Clarke, 1892c, Pl. II, figs. 17–23] of the Upper Ordovician appears to be the best expression of an intermediate form between *Obolus* (*Fordinia*) (Pl. LXIII, figs. 10, 10a–d) and the forms represented by *Dinobolus* [Hall and Clarke, 1892c, Pl. IVB] and *Trimerella* [Hall and Clarke, 1892c, Pl. IVA] of the Silurian, but it is quite probable that *Lingulasma* was not in any way intermediate between *Fordinia* and the trimerellids. It seems to represent a side branch of *Lingula*.

The line of development of the platform to Ordovician and Silurian forms seems to have been from some *Obolus*-like form, as *Fordinia* to *Neobolus* (Pl. LXXXI, figs. 2e and 2f), and thence to *Dinobolus*. I thought at one time that *Elkania* might be a possible ancestral line to the Trimerellidæ, but, after carefully considering the position of the rudimentary platforms, I concluded with Schuchert that *Elkania* was an offshoot from *Obolus* that did not leave any known descendants.

SEPTA.

The septum of the dorsal valve of the Obolidæ is usually in the form of a narrow ridge, and is not a true septum in the usual sense, which is that a septum is a thin median vertical plate of variable height, terminating freely or supporting a spondylium. Well-developed septa occur in the Syntrophiidæ as supports beneath the spondylia (Pl. CIII, figs. 3d and 3e; Pl. CIV, figs. 2c and 2d).

DENTAL PLATES.

Dental plates first appear, so far as known, in the Protremata as obscure processes supporting the teeth of the ventral valve, one on each side of the delthyrium. One of the oldest examples

is that of the Lower Cambrian *Nisusia festinata* (Pl. C, fig. 1j), where the plates form the support of the teeth and also outline a rudimentary spondylium. *Protorthis* of the Middle Cambrian has a spondylium on each side of which are the teeth supported at each of the outer angles next to the cardinal area (Pl. XCIX, fig. 3b). Dental plates undoubtedly existed in other genera of the Protremata of the Cambrian, but they have not been observed.

VASCULAR MARKINGS.

The most prominent of the vascular impressions are the pallial sinuses or main vascular canals. Usually all that is impressed on the inner surface of the valves are the two main trunks that diverge from near the apex or beak of the valves and skirt the margin of the visceral area. In rare instances the impressions of the secondary branches of the main sinuses are preserved.

ATREMATA.

None of the shells of the genera of the Paterinidæ show more than the bases of the main trunks of the vascular system, but in *Obolus* and *Lingulella* and their subgenera there are numerous illustrations of the main vascular canals and in a few instances of the secondary canals.

Obolus apollinis (Pl. VII) of the Upper Cambrian has the vascular system as well developed, judging from the impressions left by it on the interior of the valves, as in the mantle of recent *Lingula*. In the closely allied form, *Lingulella granvillensis* (Pl. XXII, figs. 1b and 1d), from the Lower Cambrian, there is every reason to think that the vascular system has reached its full development. The main vascular trunks, lateral canals, and peripheral canals are all indicated in the ventral valve (Pl. XXII, fig. 1d). Striking illustrations of the preservation of the markings of the vascular system are shown in many of the illustrations. (See Pl. VIII, fig. 1d; Pl. XII, figs. 1c, 1e, 9, and 9a; Pl. XIII, fig. 1m; Pl. XV, fig. 1i; Pl. XVII, figs. 1h and 1j; Pl. XXXVI, figs. 1c and 1d; Pl. XXXVII, fig. 1c; and Pl. XXXVIII, figs. 2b and 2d.)

In *Bicia* (Pl. L), one of the oldest of the Obolidæ, the main vascular trunks are very strong, and they are prominent in *Dicellomus* (Pl. LII, figs. 1d and 1j; Pl. LIII, figs. 1d, 2, and 4a).

NEOTREMATA.

In the Neotremata, *Obolella*, the most primitive form, has the vascular trunks developed (Pl. LIV, figs. 2g-n) on a scale comparable with those of *Obolus*, but, as is usually the case among Cambrian brachiopods, the calcareous shells do not appear to bear the impressions of the secondary canals as well as do the chitinous or phosphatic shells. The main vascular canals of *Botsfordia* (Pl. LVII, figs. 4g-m; Pl. LIX), *Linnarssonella* (Pl. LXXIX, figs. 1m-p, 2, and 2a), *Trematobolus* (Pl. LXXXIII), *Yorkia* (Pl. LXXXII, figs. 1h and 2), *Schizambon* (Pl. LXXXIV, figs. 1a, 1c, 2d, 3b, and 3c), and *Dearbornia* (Pl. LXXXII, figs. 7b and 7c) are all strongly developed. In *Acrothele* are found some of the most beautiful examples of the preservation of a highly developed system of vascular canals (Pl. LVI, figs. 1a-d, 3b, and 3c; Pl. LXI, figs. 1c and 1d). *Acrotreta* has relatively large vascular trunks (Pl. LXIV, figs. 1i, 1j, and 2c; Pl. LXV, figs. 1f, 1g, 3c, and 6; Pl. LXXIII, figs. 4c and 6), but no traces have been seen of the lateral canals. The main trunks of *Acrothyra* are also large (Pl. LXXVI, figs. 4a and 4b). *Discinopsis* (Pl. LXXXII, figs. 5a-b) has two narrow, long, main trunks that originate back of the line of the opening of the pedicle tube.

PROTREMATA.

In *Billingsella* the great size of the main vascular trunks (Pls. LXXXV-XC) is characteristic of the genus. The manner in which the anterior branches of the main trunks pass outward toward the border is finely shown in specimens of *B. plicatella* (Pl. LXXXVI, fig. 3i). The dorsal valve of *B. exprorecta* (Pl. LXXXVIII, fig. 1k) has two strong apparently main sinuses, on each side; the inner pair, however, may not be casts of the vascular sinuses, but may indicate grooves made by the path of advance of the attachments of the posterior adductor muscles.

The vascular system of *Nisusia* (Pl. C) and its subgenus *Jamesella* (Pl. CI), *Protorthis* (Pl. XCIX), and usually of *Eoorthis*, has left no traces of its presence on the shell. On some

examples of *Finkelburgia* (Pl. XCIII, figs. 1d, 1f, 2, and 2b) there are indications of large main trunks, and in *Orusia* (Pl. XCVIII, figs. 1e and 1p) narrow trunks are seen. Only one among many hundreds of specimens of *Eoorthis* (Pl. XCI, fig. 3b) shows traces of the main trunks.

Among the Syntrophiidæ, *Huenella abnormis* (Pl. CIII, figs. 2b and 2h) shows that the main trunks were of large size. I have not seen any interiors of the shells of the Strophomenidæ from the Cambrian system.

This brief review proves that the simple primitive type of the circulatory system, as developed in the main vascular canals, their laterals, and the peripheral canals of the mantle, was fully developed in Lower Cambrian time, and that this type persisted throughout Cambrian time. The modified form of the canal system of the Craniidæ has not been observed, nor has the complex canal system of the Ordovician and later orthoids [Hall and Clarke, 1892c, Pls. VA, VC, VI, and VI_A].

MUSCLE SCARS.

It is only within a few years that material has been available from Cambrian rocks that could furnish data for a description of the muscle scars and by them an outline of the muscular system of the Cambrian brachiopods.

ATREMATA.

In the Atremata this has been most thoroughly worked out for *Obolus* by Mickwitz (1896), and an outline may be found in this monograph under the description of the genus *Obolus*. The terminology used in this monograph is mentioned on page 292.

In the most primitive form of brachiopod known to me, *Rustella edsoni*, the muscle scars of the dorsal valve, so far as known, indicate that the system of scars was essentially the same as in *Obolus*. In the dorsal valve the central scars (Pl. I, fig. 1e) are preserved; also the anterior portion of the outline of the parietal band, which indicates the position of the anterolateral scars. Although we have a number of good natural casts of the interior of the ventral valve, no traces of vascular markings or muscle scars have been observed. So far as known none of the many hundreds of specimens of various species of *Micromitra* have preserved any definite outlines of the muscle scars, and the same is true of *Mickwitzia* and *Helmersenia*.

Obolus and *Lingulella* and their subgenera all have the same general grouping of the muscle scars as described under *Obolus*. For *Obolus* these are well shown in *O. apollinis* (Pl. VII); for *Lingulella* by *L. acutangula* (Pl. XVII); for the subgenus *Westonia* by *Obolus* (*Westonia*) *escasoni* (Pl. XLIX, figs. 1a, 1aa, 1c, and 1d). The same general arrangement of the muscle scars, so far as known, is found in *Bicia* (Pl. L), *Elkania* (Pl. LI), and *Obolus* (*Fordinia*) (Pl. LXIII, figs. 10a and 10c). In *Dicellomus* the central and the outside and middle lateral scars are located in front of the visceral area, as in *Obolus*, but the anterolateral and transmedian scars are combined in one large cardinal scar (Pl. LIII, fig. 1c at cl), as in *Acrotreta* (Pl. LXIV, figs. 2c and 2d); in the dorsal valve the central and anterolateral scars are as in *Obolus*, while the transmedian, outside laterals, and middle laterals appear to be grouped in one large cardinal scar (Pl. LIII, fig. 1i at cl). The combining of the muscle scars of the posterolateral region of the valves in one large scar in this genus of the Atremata foreshadows the typical large cardinal scar so characteristic of the Neotremata.

NEOTREMATA.

In *Obolella* (Pls. LIV and LV) the arrangement of the muscle scars, so far as known, is that of *Obolus*, but with a tendency on the part of the posterolateral scars to close in toward each other; this tendency is carried into effect in *Botsfordia* (Pl. LIX, figs. 1k and 1n; Pl. LVII, fig. 4k; and Pl. LXII, figs. 5g and 5i). In the dorsal valve of *Botsfordia pulchra* (Pl. LXII, fig. 5h) the transmedian and middle lateral scars appear to be distinct, but in figure 5i and in all ventral valves, figures 5g and 5j, a single large scar appears to be present. In *Linnarssonella*, which I have placed as the descendant from the *Acrotreta* stock (schematic diagram, p. 317), the posterolateral scars are all grouped in both valves in a large cardinal muscle scar (Pl. LXXIX, figs. 1k-p). The muscle scars of the central portion of the valves remain essentially as in *Obolus*.

The system of muscle scars in *Trematobolus* (Pl. LXXXIII) is, so far as known, that of *Obolus*, with a modification probably of the position of the scars of the pedicle muscles; of the latter, unfortunately, nothing is known. *Dearbornia* (Pl. LXXXII, figs. 7b and 7c) has the same arrangement of the muscle scars as *Trematobolus*, but of the muscle scars of the other genera descendant from the *Trematobolus* stock we know very little. The interiors of *Siphonotreta* (Pl. LXXXI, figs. 6c, 6d, and 6e) indicate an arrangement somewhat like that of *Trematobolus*. *Yorkia*, *Orbiculoidea* as known in the Cambrian, and *Philhedra* show nothing of the muscle scars. *Schizambon* (Pl. LXXXIV) appears to be related in its muscle scars to *Trematobolus*.

The muscle scars of *Acrothete*, *Acrotreta*, and *Acrothyra* agree in having the posterolateral scars united on each side in one large cardinal scar situated in the posterolateral region of the valves. The central and anterolateral scars of the dorsal valve are variously situated (Pl. LVIII, figs. 5f and 5h, and Pl. LX, fig. 11) in the central portion of the interior of the valve, but not more so than in the dorsal valve of *Obolus*. In the ventral valve the outside and middle laterals and the central scars are more or less contracted, and drawn back toward the small visceral area about the pedicle opening; the individual scars have not been seen except in one specimen of *Acrotreta argenta* (Pl. LXVII, fig. 5b). In this species the visceral area is unusually large and the positions of the outside lateral and central scars is shown; the anterolaterals are not delimited. Another species of *Acrotreta*, *A. ophirensis* (Pl. LXXIV, fig. 1e), has an unusually large visceral area, but, although the area of the muscle scars is defined, the individual scars can not be seen. No reference has been made to the umbonal muscle scars, as they are so rarely preserved. They are well developed and shown in *Obolus* and *Lingulella*, and it is highly probable if not certain that some form of umbonal muscle existed in all of the inarticulate brachiopods.

PROTREMATA.

The muscles of the Protremata are limited to three sets: diductors, to open the valves; adductors (centrals), to close the valves; and the pedicle muscles.

In *Kutorgina*, the atrematous progenitor type of the Protremata, the anterior and posterior adductors (equal to the anterolateral and central scars, respectively) are known in the dorsal valve (Pl. V, fig. 1h), but nothing is known of the point of attachment of the diductor muscles in the dorsal valve or of any muscles in the ventral valve. The muscle scars are preserved in *Billingsella* in the ventral valve within the area of the pseudospondylium. The diductors probably occupied the outer divisions of the tripartite pseudospondylium and the adductors the central section. This is well shown in many specimens (Pl. LXXXV, figs. 1m and 1p; Pl. LXXXVI, figs. 3g, 3i, 3j, 3k, 3m, and 4b; Pl. LXXXVII, figs. 5b, 5c, and 7; and Pl. XC, figs. 2g, 2h, and 2i). The diductors appear to have followed closely in the line of the scars of the main vascular sinuses if the tripartite pseudodeltidium is considered to have been wholly taken up by the points of attachment of the muscles. In the dorsal valve the adductor scars are often prominent (Pl. LXXXVIII, figs. 1g, 1h, 1j, and 1k), also the cardinal process to which the diductor muscles were attached. The interiors of the ventral valves have not thus far shown muscle scars.

The muscle scars of the ventral valve of *Nisusia* and its subgenus *Jamesella*, and those of *Finkelburgia*, *Orusia*, and *Protorthis*, were probably gathered on a pseudospondylium or, when the latter is not defined, on the bottom of the valve beneath the umbo, as in *Eoorthis*. In an obscure specimen of the dorsal valve of *Portorthis quacoensis* (Pl. XCIX, fig. 2d) the posterior adductor scars appear to be preserved.

In the dorsal valve of *Finkelburgia* the adductors are finely shown (Pl. XCIII, fig. 1f), also a rounded, posterior central depression in which the diductors may have been attached.

Among the Cambrian Syntrophiidae muscle scars have been discovered in *Iuenella abnormalis* of the Upper Cambrian. In the ventral valve (Pl. CIII, fig. 2b) the adductor and diductor scars are preserved on the spondylium, and dorsal valves (Pl. CIII, figs. 2f, 2i, and 2j) show the adductors in fine preservation, also the cruralium to which the diductor muscles were attached. The muscle scars of this species are of unusual interest, as the ventral valve has a spondylium to which the pedicle, the large diductor, and the smaller scars of the adductor muscles were attached.

PEDICLE TUBE AND APERTURE.

ATREMATA.

When the pedicle rests in furrows on the areas of the valves, as in *Obolus* (Pls. VII and XIV), it pertains to both valves, but with the deposition of a narrow band of shell about it on the ventral valve it strictly pertains to this valve alone, although it may still rest against the area of the dorsal valve before passing through the semitube of the ventral valve. The transition from the deep but open pedicle furrow of the ventral valve of *Obolus* to the inclosed sheath or tube of *Obolella* is found in *Dicellomus politus*. In this species there has been a deposit of shelly matter that rises up from the sides of the pedicle furrow on the ventral valve and arches slightly inward, almost forming a tube in places; what remains of this semitube is shown by figures 16A and 16B.

NEOTREMATA.

The earliest and simplest stage of development of the pedicle tube when it completely surrounded the pedicle is found in *Obolella* of the Lower Cambrian (Pls. LIV and LV). In this genus the deep pedicle furrow of the ventral valve of *Dicellomus* has been covered over just at the apex of the cardinal area so as to form a simple ring or tube about the pedicle. In the next stage, as shown by *Botsfordia* (Pls. LVII and LIX), the pedicle has advanced its opening to the front side of the apex and the tube between it and the furrow in the area is a little stronger and a trifle larger.

In *Linnarssonella* (Pls. LXXVIII and LXXIX) the opening of the pedicle tube is close to the posterior margin and the *Obolella*-like structure in both valves is very striking. This is best seen by comparing the casts of the interior of the ventral valves of *Linnarssonella* (Pl. LXXIX, figs. 3c-g) with those of *Obolella atlantica* (Pl. LV, figs. 1f-h). In both species the cast of the pedicle tube is in the same position in relation to other parts, and the external opening of the pedicle tube is at the apex above a low false cardinal area.

FIGURE 16.—*Dicellomus politus* (Hall). A, Interior of ventral valve (fsp, pseudospondylium or pedicle plate; i, transmedian scars; j, anterolateral scars; v, visceral cavity; vs, main vascular sinuses). B, Posterior portion of the interior of a ventral valve, showing a strongly developed area (fsp, pseudospondylium or pedicle plate; a, inside section of area; f, flexure line; a', outside section of area).

The specimens represented by figures 16A and 16B are from Locality 79s, Upper Cambrian "St. Croix sandstone" at Hudson, Wisconsin (U. S. Nat. Mus. Cat. Nos. 51917a and 51917b, respectively). The same figures are reproduced on page 576.

The depressed forms of *Acrothele*, with the apex near the posterior margin, appear to have been descendant from the *Obolella* stock but to have reached a stage of development more advanced than any known form of the Cambrian genus *Obolella*. *Acrothele bellula* (Pl. LVIII, figs. 5, 5a-h) of the Middle Cambrian appears to be one of the oldest forms and to have retained in its ventral valve characteristics of its obolelloid ancestors. In the ventral valve the pedicle tube penetrates the thickened apex of the shell and there is considerable space between the pedicle aperture and the posterior margin; the tube and aperture are essentially the same in all the species of *Acrothele*, differing only in details due to a rather narrow range of position and the varying thickness of the shell. The genus *Schizopholis* (Pl. LXXXI, figs. 1, 1a-c) has a more nearly vertical posterior slope and distinctly marked false area, in this respect resembling the large group of species referred to *Acrotreta*. The pedicle tube and aperture of the latter are of the same type as in *Acrothele*, differing only in form and position within a narrow range. *Acrothyra* also shows little variations. *Discinolepis* (Pl. LXXXI, figs. 3 and 3a) has the pedicle opening more advanced and appears to be a form intermediate between *Acrothele* and *Acrotreta*.

The pedicle tube of *Keyserlingia* (Pl. LXXXI, fig. 4c) apparently opens into an elongated depression in the shell back of the apex of the ventral valve; the tube is a passage through a thickened mass of shell which is deposited about the pedicle and which is especially well developed in old shells (Pl. LXXXI, figs. 4a and 4d).

PROTREMATA.

A pedicle tube or opening is found in the genus *Billingsella* of the Lower Cambrian, the characteristic opening being at the apex of the delthyrium (fig. 65, p. 750). It has not been observed in *Nisusia* (Pl. C) nor in the subgenus *Jamesella* (Pl. CI), nor in any other genus or subgenus of the Protremata of the Cambrian fauna. This may be owing to the absence of a deltidium in the adult stages of the shell found, to its being covered by the incurved beak, to the difficulty of working out or uncovering the deltidium so that it can be seen, or in all probability to the permineralization of the shell and the generally coarse nature of the sediments deposited with the shells. It may be that the opening was closed naturally in the adult stages as in some of the Ordovician *Clitambonites*. Even in *Billingsella*, where the material is abundant and well preserved, it is only rarely that an entire deltidium is obtained and very rarely that the minute pedicle opening can be seen at its apex.

OLD-AGE CHARACTERS.

I have not given special attention to old-age characters during the progress of the study of the Cambrian brachiopods. The variations due to old age during the gerontic period appear in the unusual thickening of the shell of *Obolus apollinis* (Pl. VII), but old age is not indicated on the exterior of the shell (Pl. XIV, figs. 6 and 6a). The areas of attachment of the muscles in *Obolus mickwitzii* (Pl. X) suggest old age, and the strong concentric ridges at the front of the valves is another phase of old-age conditions. *Obolus* (*Lingulobolus*) (Pl. XVI), in its thick shell, large deep muscle scars, and convex valves indicates an old-age form derived from *Obolus*. In *Keyserlingia buchi* (Pl. LXXXI, figs. 4a-e) the interior shell growth associates the species with old-age forms.

There is abundant material for study of many of the species described in this volume that may, when carefully worked up and studied, give some interesting results in relation to changes in the shell during the mature (neologic) and old-age (geratologic) periods of growth.

DISTRIBUTION*IN CAMBRIAN STRATA.

We do not know of any brachiopods in strata older than that containing the Mesonacidae or Lower Cambrian fauna. That such existed in pre-Cambrian time seems almost certain when the advanced stage of development of some of the earliest-known forms is considered.

In the following diagram the known occurrence of the families of brachiopods in strata of Cambrian age is graphically shown. The diagram is based on the data contained in the table (p. 112) giving a summary by families. The Obolidæ, with 6 genera, 9 subgenera, 186 species, and 14 varieties, has the greatest development, and this family continues into the base of the Ordovician with 4 genera, 3 subgenera, 41 species, and 1 variety. The Acrotretidæ has 6 genera, 1 subgenus, 100 species, and 20 varieties, with the greatest development in the Middle Cambrian and with a smaller representation in the Lower Ordovician. The Billingsellidæ, with 9 genera, 2 subgenera, 91 species, and 12 varieties, has a strong line of development from the upper Middle Cambrian and passes into the Ordovician, where it disappears. The three families mentioned include about 48 per cent of the genera, 80 per cent of the subgenera, 80 per cent of the species, and 79 per cent of the varieties included in the Cambrian Brachiopoda. The development of genera of the remaining families containing 3 genera or more is as follows: Paterinidæ, 3; Obolellidæ, 4; Siphonotretidæ, 6; Syntrophidæ, 3; or 16 genera of the 23 outside

of the Obolidae, Acrotretidae, and Billingsellidae, which contain 21 genera. The remaining 7 families include 7 genera.

Of the 44 genera from the Cambrian, 19 occur in the Lower Cambrian, 31 in the Middle Cambrian, and 20 in the Upper Cambrian.

FIGURE 17.—Diagram illustrating known distribution of families in Cambrian strata.

EVOLUTION OF THE CAMBRIAN BRACHIOPODA.

SCHEMATIC DIAGRAM.

In order to formulate, so far as possible, in a graphic manner my conception of the evolution and lines of descent of the Cambrian Brachiopoda, gained by the investigations described in this monograph, a schematic diagram (fig. 18) has been prepared.

This diagram is necessarily tentative and incomplete, but it will serve to point out my present conceptions of the lines of evolution of the various genera, and it shows clearly the very rapid development of the primitive atrematous genera in early Cambrian time.

The genera identified from each of the three divisions of the Cambrian may be ascertained by glancing at the columns headed Lower, Middle, and Upper Cambrian for the generic and subgeneric names included in each column.

The most primitive but not the oldest species known to me from the Cambrian formations is *Rustella edsoni* (Pl. I, figs. 1, 1a-e). This is found in association with *Olenellus thompsoni* in Vermont, where it occurs at nearly the summit of the Lower Cambrian, and not low down toward the base of the Cambrian system. Probably the oldest-known brachiopod, or the species lowest in the stratigraphic series, is *Trematobolus excelsis* (Pl. LXXXII, figs. 8, Sa-d). This is far advanced in development and must have had a long line of descent from the protogulum stage. Another very ancient type is *Micromitra*. A species with ornamented surface (*M. (Iphidella) louise*) occurs 2,850 feet down in the Lower Cambrian of the Canadian Rockies and *Micromitra (Iphidella) pannula* (Pl. IV) is abundant in the upper portion of the Lower Cambrian. *Micromitra (Paterina) labradorica* (Pl. II) is found deep in the Lower Cambrian of New Brunswick

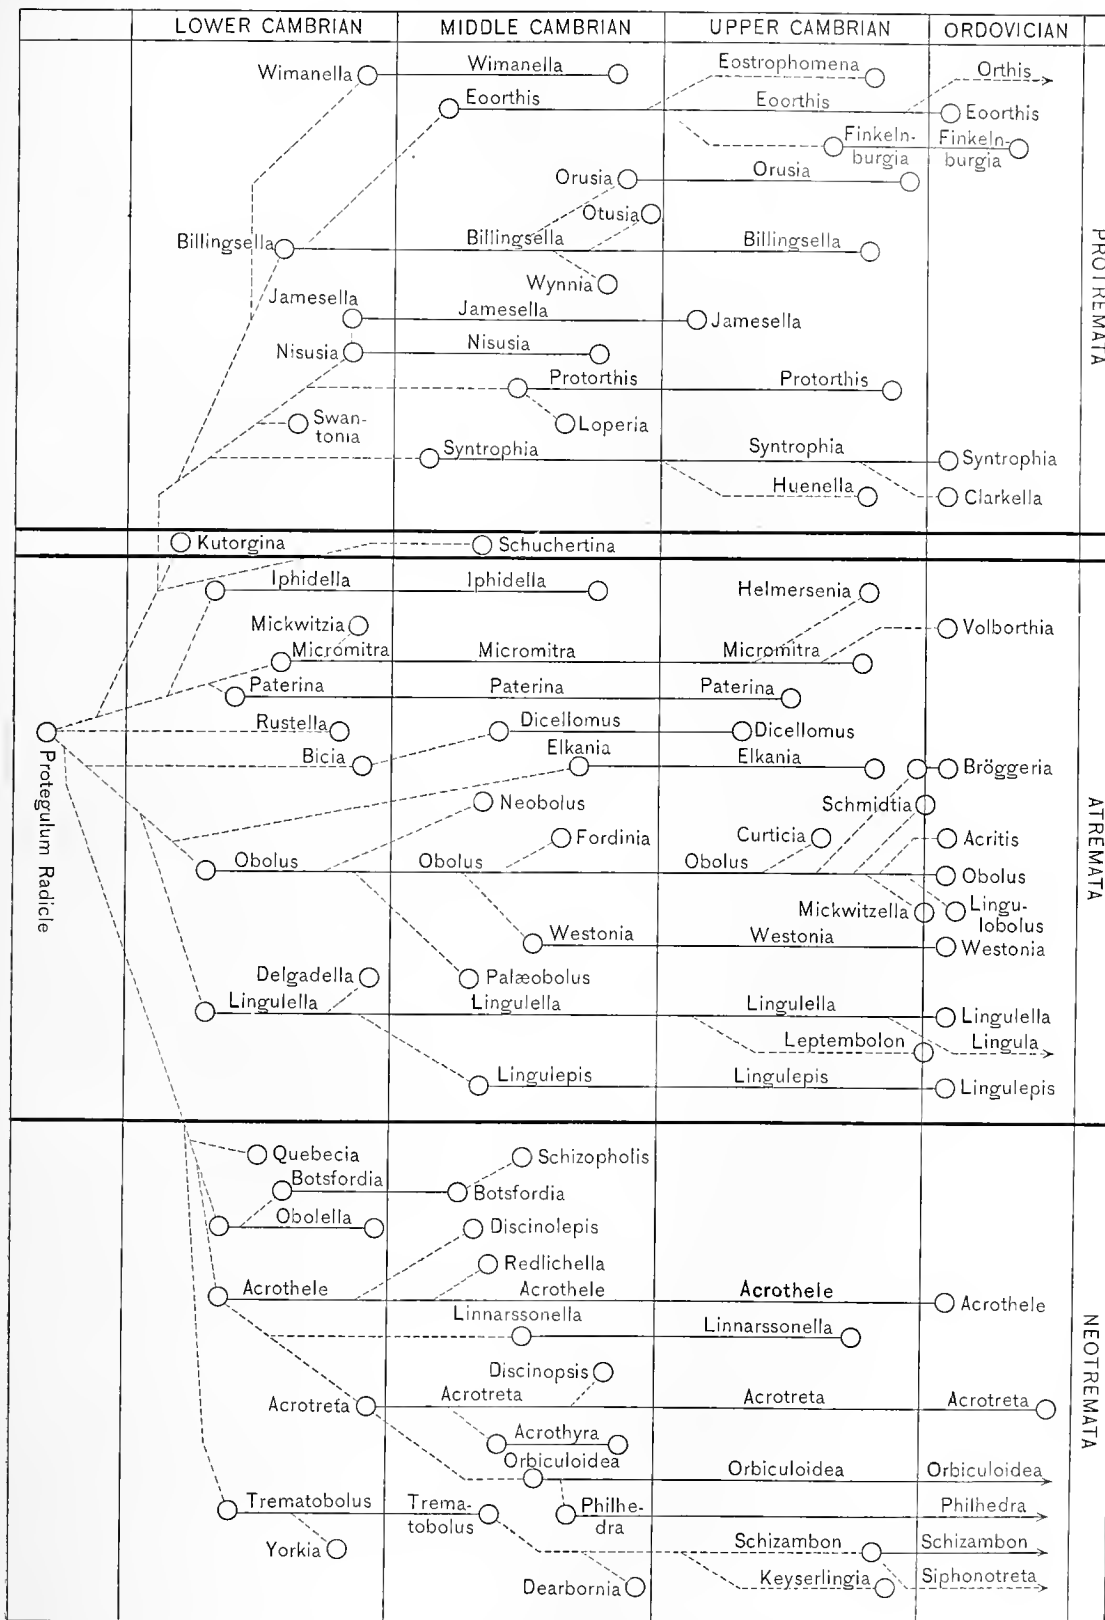

FIGURE 18.—Schematic diagram of evolution of Cambrian Brachiopoda.

and is the oldest brachiopod known from the Atlantic Province. *Bicia* (Pl. L), *Obolella* (Pls. LIV and LV), *Quebecia* (Pl. CIV), *Botsfordia cœlata* (Pl. LIX), *Acrothele bellapunctata* (Pl. LVII, figs. 3, 3a-b), *A. decipiens* (Pl. LVIII, figs. 3, 3a-d), *A. woodworthi* (Pl. LX, fig. 6), *Acrotreta emmonsii* (Pl. LXV, fig. 6), *A. primæva* (Pl. LXIX, figs. 1, 1a-f), and *Yorkia* (Pl. LXXXII) occur with other forms in the upper portion of the Lower Cambrian fauna. All of these examples of inarticulates indicate that the brachiopod fauna had advanced far in its evolution in Lower Cambrian time. Among the progenitors of the Protremata, *Kutorgina* (Pl. V) occurs in the Mesonacidæ fauna, and *Schuchertina* (Pl. LI) of the Middle Cambrian probably springs from the *Kutorgina* stock in Lower Cambrian time. Among the articulates we find, of the order Protremata in the Lower Cambrian, several species of *Billingsella* (Pls. LXXXVI-LXXXIX), *Nisusia* (Pls. C and CI), and *Swantonina* (Pl. CIV), all from the upper zone of the Mesonacidæ fauna. (See lists of genera and species, pp. 98-109.)

ATREMATA.

The most primitive form of the Atremata known to me is *Rustella edsoni* (Pl. I, figs. 1, 1a-e) of the upper portion of the Lower Cambrian terrane. It is without a false cardinal area, and there is only a slight indication of a pedicle furrow; some of the less well-preserved shells suggest the protegulum stage of the Brachiopoda. *Mickwitzia* (Pl. VI, figs. 1'' and 3), *Helmersenina* (Pl. LXIII, figs. 7b and 7d), and *Volborthia* (Pl. I, figs. 6 and 6e) have an obscurely defined false cardinal area on the ventral valve. In *Helmersenina* the pedicle opening is produced by the gaping of the valves; in *Volborthia* (fig. 33, p. 366) it is produced by the bulging of the cardinal margins. In *Micromitra* (Pls. II, III, and IV) the posterior margins of the valves may be nearly closed as in *M. pealei* (Pl. III, figs. 3b and 3e'), or have a more or less open delthyrium as in *M. (Iphidella) pannula* (Pl. IV, figs. 1d, 1f, 2a'', 2b', 4a', and 4d'). In *Curticia* (Pl. I, figs. 2', 2b, 2a'', and 2d) the open delthyrium is more developed than in *Micromitra*, although the cardinal area is not outlined. *Curticia* appears to be a form intermediate in character between *Micromitra* of the Paterinidæ and *Obolus* of the Obolidæ. It shows no trace of a pseudodeltidium or any closing of the delthyrium by an extension of the area across it. In the graphic systematic scheme (p. 317) it is placed as a family descendant from *Obolus*.

In the diagram on page 317 the lines of descent of the various genera are graphically outlined, but our information is often so fragmentary that the scheme is necessarily imperfect. In this the *Rustella* type of the upper Lower Cambrian is assumed as the known form that most nearly approaches the protegulum stage or the first stage in which it would be possible to have a brachiopod preserved as a fossil. From the pre-*Rustella* radicle *Micromitra* developed in early Cambrian time and continued nearly to the close of the Upper Cambrian, giving rise in the Lower Cambrian to *Mickwitzia* and in the Upper Cambrian to *Helmersenina* and *Volborthia*.

Obolus, branching from the *Rustella* protegulum radicle, is first known in the Lower Cambrian a little later than *Micromitra*. It persisted on into the Ordovician, giving rise in early Middle Cambrian time to its subgenera *Palæobolus* and *Westonia*, in late Middle Cambrian time to *Fordinia* and to *O. (Acritis?) rugatus*. Other subgenera, *Schmidtia*, *Bröggeria*, and *Mickwitzella*, appeared in late Upper Cambrian or early Ordovician time. *Bicia* is taken from the pre-*Obolus* radicle. *Dicellomus* appears in central Middle Cambrian strata and continues into the Upper Cambrian. It probably originated in the *Bicia* phylum in Lower Cambrian time. *Elkania* begins in central Middle Cambrian strata and continues well into the Upper Cambrian. It appears to have been an offshoot from *Obolus* without known direct descendants. *Neobolus*, with its peculiar platforms pointing to the future Trimerellidæ, is probably a descendant from some Lower Cambrian form that branched off from *Obolus*. The descendants of *Neobolus*, if such existed, are unknown in the late Middle and Upper Cambrian. *Curticia* is given as an offshoot from *Obolus* in Upper Cambrian time and *Lingulobolus* in the Lower Ordovician. *Fordinia* appears to have been an offshoot from *Obolus* in Middle Cambrian time and to have disappeared without descendants.

It is assumed that *Lingulella*-like forms developed from primitive *Obolus* in early Cambrian time, since the genus is first known from the lower portion of the Lower Cambrian and is known to occur throughout the Cambrian and into the Ordovician. The subgenus *Lingulepis* appears in Middle Cambrian time and continues on into the Lower Ordovician. Little is known of *Delgadella* of the Lower Cambrian, but from its form it is referred to the *Lingulella* phylum. *Lingula* is probably descendant from *Lingulella* in late Cambrian time. *Lingulella davisii* (Pl. XXXI, figs. 6e, 6f) is quite similar to *Lingula*, as are *Lingulella lens*, *L. concinna* (Pl. XXXIII), and other Upper Cambrian species. The subgenus *Leptembolon* branches off from *Lingulella* in late Upper Cambrian time.

Matthew [1902b, p. 98] has given a diagram showing "Conjectural Lines of Descent of the Canadian Oboli with Reference to the Oldest Known Atremata." This diagram and the discussion following it are based upon Matthew's observations in the Cambrian section of New Brunswick and Nova Scotia and his interpretation of the genera and species. The greater opportunity offered by larger collections from a much wider field has so changed the data upon which his conclusions were based that I shall not enter into a discussion of them.

Kutorgina (Pl. V) is assumed to have branched off from the *Micromitra* radicle in pre-Cambrian time, and from its line of descent or radicle *Schuchertina* (Pl. LI, figs. 6, 6a-m) is taken off. Both of these genera are placed on the border line between the Atremata and Protremata.

NEOTREMATA.

The progressive increase in the differences in form and the relations of the two valves in the genera of the Neotremata is best seen by a glance at the diagram on page 317. In this an *Obolella*-like type is descendant from a simple form like the *Rustella* radicle and from this radicle the Acrotretidæ diverges. *Acrothele*, with its great vertical range from the Lower Cambrian to the Ordovician and its wide geographic distribution, is the oldest and simplest form; *Acrotreta* is derived from *Acrothele*, and is first known toward the close of the Lower Cambrian and continues through to the Ordovician; from the *Acrotreta* branch *Acrothya* and *Discinopsis* diverged in Middle Cambrian time. *Linnarssonella* is assumed to have branched off from the *Acrotreta* radicle, and it is known to have continued from the central Middle Cambrian to later Upper Cambrian time. Another branch from *Acrotreta* leads to *Orbiculoidea* in the central Middle Cambrian, which continues on into the Ordovician. A shell doubtfully identified as *Philhedra* occurs in the Middle Cambrian. If correctly identified it represents the Craniidæ in the Cambrian fauna.

Botsfordia is an offshoot from *Obolella* in the central Lower Cambrian, and I have assumed it to be the progenitor of *Schizopholis* of the Middle Cambrian. *Quebecia* of the middle Lower Cambrian is tentatively shown to be derived from the *Obolella* radicle.

Another branch is *Trematobolus*, which is assumed to be the direct progenitor of the Siphonotretidæ as an offshoot of the *Obolella* primary stock. *Yorkia* is the first known branch from *Trematobolus* in Lower Cambrian time. *Dearbornia*, as known, is limited to the upper portion of the Middle Cambrian.

PROTREMATA.

The ancestral types of the true Protremata are, so far as at present known, *Nisusia* and *Billingsella*. These appear to have come from the radicle leading from *Micromitra* to *Kutorgina* of the Lower Cambrian. *Kutorgina* is placed on the border line between the Atremata and Protremata without direct descendants.

Schuchertina (Pl. LI, figs. 6, 6a-m) has a calcareous shell, smooth outer surface, poorly defined cardinal areas, open delthyrium, and large muscle areas on the ventral valve. It suggests one of the transition forms between *Kutorgina* and *Nisusia*, but as its stratigraphic position is in the central Middle Cambrian, far above and much later in time than the early forms of the lines of descent of the Protremata, it is placed on the border line without descendants.

The earliest representatives of the Nisusiinae are *Nisusia* and its subgenus *Jamesella*; both occur in the upper portion of the Lower Cambrian. *Nisusia* is unknown later than the upper portion of the Middle Cambrian, and *Jamesella* is unknown above the base of the Upper Cambrian. *Protorthis*, along with its subgenus *Loperia*, is first known in the central portion of the Middle Cambrian; it disappears toward the close of the Upper Cambrian. *Billingsella* is known from the central Lower Cambrian and on to nearly the close of the Upper Cambrian.

Of the genera of the Billingsellidæ other than *Billingsella*, *Wynnina* occurs in the Middle Cambrian. *Orusia* appears in the upper portion of the Middle Cambrian and continues well up into the Upper Cambrian, and *Otusia* is found in the upper part of the Middle Cambrian. None of these genera appear to have had descendants in Ordovician time. *Wimanella*, although a more primitive form than *Billingsella*, is not known to occur as low down in the Lower Cambrian, and its upper range is only to the upper portion of the Middle Cambrian. It is derived from the *Billingsella* radicle.

Eoorthis is first known from the lower portion of the Middle Cambrian and continues through the Upper Cambrian into the Ordovician. Its line of evolution through *Billingsella* appears to have been from the same radicle as *Nisusia*, which occurs in the upper portion of the Lower Cambrian. The genus *Finkelburgia* is derived from *Eoorthis* in the lower portion of the Upper Cambrian. The Ordovician genus *Orthis* is assumed to have developed from *Eoorthis* in late Cambrian time, and *Eostrophomena* in the early Upper Cambrian.

Syntrophia, beginning in the lower Middle Cambrian, continues into the Ordovician, and appears to have descendants in *Clarkella* and in *Huenella*.

Swantonina suggests the Rhynchonellidæ in form, but it has a spondylium and it may have been the progenitor of both *Syntrophia* and *Protorthis*. It is represented in the diagram as an offshoot from the radicle of *Nisusia*, without descendants. A review of the characters of the various subgenera of *Orthis* from the Ordovician strata leads us to expect to find representatives of *Dinorthis* in the Cambrian. According to Hall and Clarke [1892a, p. 195] this form is characterized by having the ventral valve depressed so that it is flat or concave over the pallial region, in this respect resembling *Hebertella* [Hall and Clarke, 1892a, p. 198]. Among Cambrian forms *Protorthis* (*Loperia*) *dugaldensis* (Pl. XCIX, figs. 5, 5a-h) of the Middle Cambrian has the depressed ventral valve, but otherwise it differs from *Dinorthis* in having a spondylium in the ventral valve and in the absence of a cardinal process in the dorsal valve. Thus far there appear to be no representatives of *Orthis*, *Plectorthis*, *Orthostrophia*, *Platystrophia*, *Heterorthis*, *Bilobites*, *Dalmanella*, or other Ordovician or Silurian orthoids among the Cambrian species. In endeavoring to trace a genetic connection between the Cambrian Billingsellidæ and the Orthidæ of the Ordovician we are met at once with the great hiatus caused by lack of material for study and comparison from the formations between the Upper Cambrian and the Middle Ordovician. The Orthidæ of the Middle Ordovician include a large group of brachiopods, differing radically from the Billingsellidæ in shell structure, whose ancestral line in the Lower Ordovician and Upper Cambrian is unknown. That this break will be filled is highly probable, but meantime the more or less conjectural lines of descent of various authors must be carefully reviewed in each case in connection with all the stratigraphic and paleontologic evidence afforded by all known Lower Ordovician formations, especially in the American and European areas. Systematic studies now in progress by members of the United States Geological Survey may afford much valuable information that will be of service in this connection.

CLASSIFICATION.

That we may have a graphic illustration to aid in description, the following table and scheme are inserted. The ordinal classification of Beecher [1891], with emendations, is taken as the basis for the orders, while the arrangement of superfamilies is practically that of Schuchert [1897], with such emendations and additions as greater information has rendered necessary.

Table of classification of Brachiopoda.

Order **ATREMATA** Beecher [1891, p. 354].

(Emended Schuchert [1897, p. 119] and Walcott [1908e, p. 142].)

Primitive inarticulate corneous or calcareophosphatic Brachiopoda with the pedicle emerging more or less freely between the two valves. Growth takes place in general around the anterior and lateral margins. Specialized forms show tendency to develop rudimentary articulation. Delthyrium originally unmodified, in later genera modified by pseudodeltidia and pseudochilidia, or by thickened, striated, and more or less furrowed or even cleft vertical cardinal margins, the ventral cleft in most specialized forms tending to inclose the pedicle and finally restrict it to the ventral valve; when completely so the genera are referred to the order Neotremata.

Superfamily **RUSTELLACEA** Walcott [1908e, p. 143].

Primitive, thick-shelled, corneous or calcareophosphatic Atremata developing more or less of pseudodeltidia and pseudochilidia.

Family **RUSTELLIDÆ** Walcott [1908e, p. 143].

Primitive Rustellacea with the delthyrium small, open, and not much modified by pseudodeltidia or pseudochilidia. Muscle scars and vascular sinuses not well defined in the shell.

Rustella Walcott [1905a, p. 311].

Family **PATERINIDÆ** Schuchert [1893, p. 151].

(Emended Schuchert [1897, p. 119] and Walcott [1908e, p. 143].)

Progressive Rustellacea with the delthyrium more or less closed by pseudodeltidia or pseudochilidia.

Mickwitzia Schmidt [1888, p. 24].

Micromitra Meek [1873, p. 479].

(*Paterina*) Beecher [1891, p. 345].

(*Iphidella*) Walcott [1905a, p. 305].

Volborthia Kutorga [1848, p. 277].

(?) *Helmersenina* Pander [1861, p. 48].

Superfamily **OBOLACEA** Schuchert [1896, p. 305].

(Emended Schuchert [1897, p. 119] and Walcott [1908e, p. 143].)

Derived (in Rustellacea), progressive, thick-shelled, calcareophosphatic or corneous Atremata without pseudodeltidia and pseudochilidia. Rounded or linguloid in outline, more or less lens-shaped, and fixed by a short pedicle throughout life to extraneous objects.

Family **CURTICIDÆ** Walcott and Schuchert [Walcott, 1908e, p. 143].

Primitive Obolacea with a high well-defined delthyrium. Interior characters much as in Obolidæ.

Curticia Walcott [1905a, p. 319].

Family **OBOLIDÆ** King [1846].

(Emended Schuchert [1897, p. 119] and Walcott [1908e, p. 143].)

Derived, progressive Obolacea with thickened, striated, vertical cardinal areas traversed by pedicle grooves. Muscles and vascular trunks strongly impressed in the valves.

Subfamily **OBOLINÆ** Dall [1870, pp. 154 and 161].

(Emended Walcott [1908e, p. 143].)

Primitive Obolidæ with the pedicle grooves more or less shallow or deeply rounded, but never tending to form a sheath or to completely restrict the pedicle opening to the ventral valve. The radicle of the Trimerellidæ, by way of the Neobolinæ, appears to be in this subfamily in the thick-shelled Middle Cambrian forms of *Obolus* (s. s.).

- Obolus* Eichwald [1829, p. 274].
 (*Bröggeria*) Walcott [1902, p. 605].
 (*Palæobolus*) Matthew [1895b, p. 201].
 (*Fordinia*) Walcott [1908d, p. 64].
 (*Lingulobolus*) Matthew [1895b, p. 260].
 (*Mickwitzella*) Walcott [1908d, p. 70].
 (*Acritis*) Volborth [1869, p. 212].
 (*Schmidtia*) Volborth [1869, p. 208].
 (*Westonia*) Walcott [1901, p. 683].
Lingulella Salter [1866b, p. 333].
 (*Leptembolon*) Mickwitz [1896, p. 199].
 (*Lingulepis*) Hall [1863, p. 129].
Delgadella Walcott [1908e, pp. 142 and 144].

Subfamily **ELKANIINÆ** Walcott and Schuchert [Walcott, 1908e, p. 144].

Divergent Obolidæ with posterior or marginal (not central) platforms, to which are attached the central and outside and middle lateral muscles.

- Elkania* Ford [1886b, p. 325].

Subfamily **NEOBOLINÆ** Walcott and Schuchert [Walcott 1908e, p. 144].

Progressive Obolidæ with posterior platforms, to which were probably attached the central and outside and middle lateral muscles. Subfamily apparently progressive from the Obolinæ to the Trimerellidæ, though the platform is posterior and not subcentral as in the trimerelloids.

- Neobolus* Waagen [1885, p. 756].

Subfamily **BICIINÆ** Walcott and Schuchert [Walcott, 1908e, p. 144].

Progressive Obolidæ with the pedicle restricted to the ventral valve and more or less inclosed by a pedicle tube, and with rudimentary articulation. The transgressing stock from the Atremata to the Neotremata (Obolellidæ).

- Bicia* Walcott [1901, p. 676].
Dicellomus Hall [1873, p. 246].

Superfamily **KUTORGINACEA** Walcott and Schuchert [Walcott, 1908e, p. 144].

Progressive, thick-shelled, almost calcareous atrematous-like shells, tending to be transverse and developing rudimentary articulation, more or less rudimentary cardinal areas, pseudodeltidia, and muscle scars prophetic of the Protremata. Derived out of Rustellacea.

Family **KUTORGINIDÆ** Schuchert [1893, p. 151].

(Emended Schuchert [1897, p. 131] and Walcott [1908e, p. 145].)

Progressive transverse Kutorginacea with rudimentary cardinal areas, great delthyrial opening, rudimentary articulation, and immature pseudodeltidia. Muscle scars prophetic of the Strophomenacea.

- Kutorgina* Billings [1861b, p. 9].

Family **SCHUCHERTINIDÆ** Walcott [1908e, p. 145].

Primitive round Kutorginacea with small cardinal areas. Externally like *Obolus*, with an open subtriangular delthyrium which apparently is without a pseudodeltidium. Muscle scars and vascular markings prophetic, through the Billingsellidæ, of the Strophomenacea.

- Schuchertina* Walcott [1905a, p. 323].

Order **NEOTREMATA** Beecher [1891, p. 354].

(Emended Schuchert [1897, p. 129] and Walcott [1908e, p. 145].)

Derived and specialized inarticulate Brachiopoda (through the Obolidæ of the Atremata), as a rule more phosphatic than calcareous, more or less cone-shaped, with the pedicle emerging during life through a perforation or sheath in the ventral valve, or a triangular more or less

open cleft, or only so in the youngest-shelled stage, after which the ventral valve becomes attached by a pedicle to foreign objects. Pedicle cleft in derived forms modified by a listrium. Pseudodeltidia and pseudochilidia as a rule not well developed.

Superfamily **SIPHONOTRETACEA** Walcott and Schuchert [Walcott, 1908e, p. 145].

Primitive, thick-shelled, calcareous or corneous, oboloid Neotremata, with the pedicle passing through a ventral sheath, the aperture of which may remain apical and circular in outline, or it may become elongate through resorption by passing anteriorly through the protegulum and umbo of the shell. A listrium is not developed. Dorsal protegulum marginal.

Family **OBOLELLIDÆ** Walcott and Schuchert [Walcott, 1908e, p. 145].

Primitive Siphonotretacea with the pedicle emerging through a small circular perforation in the apex of the ventral valve, posterior to the protegulum. Derived out of the Obolidæ.

Obolella Billings [1861b, p. 7].

(*Glyptias*) Walcott [1901, p. 675].

Botsfordia Matthew [1891, p. 148].

Schizopholis Waagen [1885, p. 752].

(?) *Quebecia* Walcott [1905a, p. 320].

Family **SIPHONOTRETIDÆ** Kutorga [1848, p. 253].^a

(Emended Schuchert [1897, p. 130] and Walcott [1908e, p. 146].)

Progressive Siphonotretacea with the circular or elongate pedicle opening at the apex or passing by resorption anteriorly through the protegulum and the umbo of the shell.

Yorkia Walcott [1897b, p. 714].

Dearbornia Walcott [1908d, p. 78].

Trematobolus Matthew [1893a, p. 276].

Schizambon Walcott [1884b, p. 69].

Siphonotreta de Verneuil [1845, p. 286].

Keyserlingia Pander [1861, p. 46].

Superfamily **ACROTRETACEA** Schuchert [1896, p. 308].

(Emended Schuchert [1897, p. 129] and Walcott [1908e, p. 146].)

Progressive Neotremata with corneous or calcareocorneous shells. The pedicle opening is a simple, circular, more or less conspicuous perforation through the apex of the ventral valve. Dorsal protegulum marginal.

Family **ACROTRETIDÆ** Schuchert [1893, p. 150].

Same characters as superfamily.

Subfamily **ACROTRELINÆ** Walcott and Schuchert [Walcott, 1908e, p. 146].

Depressed large Acrotretidæ.

Acrothele Linnarsson [1876, p. 20].

(*Redlichella*) Walcott [1908d, p. 89].

Discinolepis Waagen [1885, p. 749].

Subfamily **ACROTRETINÆ** Matthew [1903, pp. 74 and 91].^b

Small Acrotretidæ with more or less high ventral valves.

Linnarssonella Walcott [1902, p. 601].

Acrotreta Kutorga [1848, p. 275].

Acrothyra Matthew [1901b, p. 303].

Discinopsis (Matthew MS.) Hall and Clarke [1892c, p. 105].

^a Described as Siphonotretææ.

^b Wrongly credited to Walcott and Schuchert [Walcott, 1908e, p. 146].

Superfamily **DISCINACEA** Waagen [1885].

(Emended Schuchert [1897, p. 130] and Walcott [1908e, p. 146].)

Derived Neotremata with phosphatic shells, a listrium modifying the pedicle slit, and without pseudodeltidia and false cardinal areas. Dorsal protogulum usually subcentral.

Family **DISCINIDÆ** Gray [1840].

(Emended Schuchert [1897, p. 130] and Walcott [1908e, p. 146].)

Discinacea with an open pedicle notch in early life in the posterior margin of the ventral valve, which is closed posteriorly during neanic growth, leaving a more or less long, narrow slit partly closed by the listrium.

Orbiculoidea d'Orbigny [1847].Superfamily **CRANIACEA** Waagen [1885].

Cemented calcareous specialized Neotremata without pedicle or anal openings at maturity.

Family **CRANIIDÆ** King [1846].

Craniacea with the pedicle functional probably only during nepionic growth.

Philhedra Koken [1889, pp. 465, 467].Order **PROTREMATA** Beecher [1891, p. 355].

(Emended Schuchert [1897, p. 131] and Walcott [1908e, p. 147].)

Progressive (though atrematous Kutorginacea), articulate calcareous Brachiopoda with well-developed cardinal areas. The pedicle opening is restricted to the ventral valve throughout life or during early growth, and is often modified and more or less closed by a deltidium. Often there is a chilidium. Brachia unsupported by a calcareous skeleton other than crura.

Superfamily **ORTHACEA** Walcott and Schuchert [Walcott, 1908e, p. 147].

Derived, progressive Protremata. Cruralia and rudimentary spondylia (pseudospondylia) free or cemented (through sessility) directly to the valves. Sometimes without deltidia and chilidia. Cardinal process more or less well developed except in the most primitive genera.

Family **BILLINGSELLIDÆ** Schuchert [1893, p. 152].

(Emended Schuchert [1897, p. 132] and Walcott [1908e, p. 147].)

Primitive Orthacea with an open or more or less closed delthyrium. Cardinal process well developed, rudimentary, or absent. Usually with a clearly defined pseudospondylium, to which the muscles of the ventral valve were attached. Shell structure dense, granular, lamellar, nonfibrous.

Subfamily **NISUSIINÆ** Walcott and Schuchert [Walcott, 1908e, p. 147].

Primitive Orthacea with more or less well-developed deltidia and with or without rudimentary chilidia. Spondylia and cruralia rudimentary or small and not supported by septa. Cardinal process rudimentary or absent.

Nisusia Walcott [1905a, p. 247].*(Jamesella)* Walcott [1905a, p. 252].*Protorthis* Hall and Clarke [1892c, p. 273].*(Loperia)* Walcott [1905a, p. 287].Subfamily **BILLINGSELLINÆ** Walcott [1908e, p. 148].^a

Primitive Orthacea very much like Nisusiinæ, but without true spondylia and cruralia. There is a more or less well-developed cardinal process except in Lower Cambrian forms.

Wimanella Walcott [1908d, p. 98].*Billingsella* Hall and Clarke [1892b, p. 230].*Orusia* Walcott [1905a, p. 273].*Otusia* Walcott [1905a, p. 246].*Wynnina* Walcott [1908e, pp. 142 and 148].^a This subfamily is wrongly referred to Schuchert, 1893, by Walcott [1908e, p. 148].

Subfamily **EOORTHEINÆ** Walcott [1908e, p. 148].

Derived Orthacea nearly always with large open delthyria; deltidia and chilidia occasionally retained throughout life, but more often only in the younger-growth stages. Cardinal process well developed. Shell structure dense, granular, and with punctate lamellæ.

Eoorthis Walcott [1908d, p. 102].

Finkelburgia Walcott [1905a, p. 277].

Superfamily **STROPHOMENACEA** Schuchert [1896, p. 312].

(Emended Schuchert [1897, p. 131] and Walcott [1908e, p. 148].)

Derived, progressive, terminal Protremata, out of Orthacea (Billingsellidæ). Deltidia and chilidia nearly always well developed. Cardinal process always well developed.

Family **STROPHOMENIDÆ** King [1846].

Subfamily **RAFINESQUINÆ** Schuchert [1893, p. 153].

(Emended Schuchert [1897, p. 132] and Walcott [1908e, p. 148].)

Strophomenoids having generally a convex ventral and a concave or nearly flat dorsal valve.

Eostrophomena Walcott [1905a, p. 256].

Superfamily **PENTAMERACEA** Schuchert [1896, p. 320].

(Emended Schuchert [1897, p. 134] and Walcott [1908e, p. 148].)

Specialized Protremata with well-developed free or supported spondylia and cruralia. Deltidia and chilidia usually absent.

Family **SYNTROPHIIDÆ** Schuchert [1896, p. 320].

(Emended Schuchert [1897, p. 135] and Walcott [1908e, p. 148].)

Primitive Pentameracea with long, straight cardinal areas.

(?) *Swantonia* Walcott [1905a, p. 296].

Syntrophia Hall and Clarke [1892c, p. 270].

Huenella Walcott [1908d, p. 109].

Clarkella Walcott [1908d, p. 110].

DESCRIPTION OF GENERA AND SPECIES.

Order ATREMATA Beecher.

[*a*, without; and *ερημα*, perforation.]

Superfamily RUSTELLACEA Walcott.

Family RUSTELLIDÆ Walcott.

Genus RUSTELLA Walcott.^a

Rustella WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 311. (Mentioned as a new genus, the type species being described.)

Rustella WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of genus.)

This genus is founded on *Rustella edsoni* Walcott. It appears to be the most primitive form of brachiopod known. The single specimen of *Rustella? major* (Matthew) does not add to our knowledge of this genus, and it may belong to some other genus.

The generic name is given in memory of William P. Rust, of Trenton Falls, Oneida County, New York, whose collections from the Lower Cambrian strata of Georgia, Franklin County, Vermont, were the most extensive and the material the finest obtained there, so far as known to me.

RUSTELLA EDSONI Walcott.

Plate I, figures 1, 1a-e.

Obolella (Kutorgina) cingulata BILLINGS (in part), 1861, Geol. Survey Canada, Paleozoic Fossils, vol. 1, p. 8, fig. 9 (not figs. 8 and 10, which represent specimens of the true *Kutorgina cingulata*). (Described and discussed as a new species.)

Obolella (Kutorgina) cingulata BILLINGS (in part), 1861, Report on the Geology of Vermont, vol. 2, p. 948, fig. 348 (not figs. 347 and 349). (Copy of preceding reference.)

Obolella (Kutorgina) cingulata BILLINGS (in part), 1862, Report on the Economic Geology of Vermont, by Hager, p. 220, fig. 348 (not figs. 347 and 349). (Copy of preceding reference.)

Obolella cingulata BILLINGS, 1863, Geol. Survey Canada, Fifteenth Rept. Progress, p. 284, fig. 287c (not figs. 287a and 287b, which represent specimens of the true *Kutorgina cingulata* and are copied from Billings, 1861b, p. 8, figs. 8 and 10, respectively). (No text reference. Fig. 287c is copied from Billings, 1861b, p. 8, fig. 9.)

Kutorgina cingulata WALCOTT (in part) [not (BILLINGS)], 1886, Bull. U. S. Geol. Survey No. 30, p. 103, Pl. IX, figs. 1g and 1h (not figs. 1, 1a-f, which represent specimens of the true *Kutorgina cingulata*). (Specimens now referred to *Rustella edsoni* are here mentioned in the discussion of *Kutorgina cingulata* as representing a possible distinct species. The specimens represented by figs. 1g and 1h are redrawn in this monograph, Pl. I, figs. 1a and 1, respectively.)

Kutorgina cingulata WALCOTT (in part) [not (BILLINGS)], 1891, Tenth Ann. Rept. U. S. Geol. Survey, p. 609, Pl. LXIX, figs. 1g and 1h (not figs. 1, 1a-f, which represent specimens of the true *Kutorgina cingulata*). (No text reference. Figs. 1g and 1h are copied from figs. 1g and 1h of the preceding reference.)

Rustella edsoni WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 311-312. (Described and discussed as below as a new species.)

General form subcircular, biconvex. Ventral valve moderately convex, with the apex at the margin immediately above a low arch in the posterior margin. Surface smooth except for concentric growth lines and low ridges that in some shells are quite prominent. A shallow, broad, rudimentary pedicle groove occurs beneath the apex and on a slightly flattened space adjoining the posterior margin. Dorsal valve about as convex as the ventral and with the apex marginal. The interior of the valve shows two rounded depressions beneath the umbo with a slight, narrow groove between them; a little in advance the outlines of the central muscle scars occur; rather strong but faintly indicated radiating lines occur toward the front.

^a Before *Rustella* was proposed by Walcott [1905a, p. 311] the species now included under the genus were placed in the following genera:

Obolella (Kutorgina) Billings [1861b, p. 8; 1861c, p. 948; 1862e, p. 220].
Obolella Billings [1863, p. 284].
Kutorgina Walcott [1886b, p. 103].

Obolus Matthew [1890, p. 155].
Kutorgina Walcott [1891a, p. 609].
Mickwitzii Mickwitz [1896, p. 23].

Observations.—This shell was identified as the dorsal valve of *Kutorgina cingulata* by Billings [1861b, p. 8, fig. 9] and as the ventral valve of the same species by myself [1886b, p. 102, Pl. IX, figs. 1g and 1h, and 1891a, p. 609, Pl. LXIX, figs. 1g and 1h]. They were considered as distorted, flattened shells. Better material shows them to represent one of the simplest forms of brachiopod known; with the exception of the rudimentary pedicle furrow and area there is nothing more than the gaping valve, much like Charles E. Beecher's ideal "*Paterina*" [1891, p. 345].

The specific name is given in recognition of the excellent work of Mr. George Edson, of St. Albans, Vermont, in collecting the Lower Paleozoic fossils of that region.

FORMATION AND LOCALITY.—Lower Cambrian: (25)^a Sandstone just above Parker's quarry, near Georgia; and (319r) on the Bullard farm about 2 miles (3.2 km.) east of Swanton; both in Franklin County, Vermont.

(392o) Arenaceous limestone collected somewhere in Vermont (exact location unknown).

(49) Sandstone on Codorus Creek, 0.125 mile (0.2 km.) below Meyer's mill, near Emigsville; and (49a) sandstone on the Liverpool road, south of the schoolhouse, 3 miles (4.8 km.) northwest of York; both in York County, Pennsylvania.

RUSTELLA? MAJOR (Matthew).

Text figure 19.

Obolus? major MATTHEW, 1890, Trans. Roy. Soc. Canada for 1889, 1st ser., vol. 7, sec. 4, No. 12, p. 155, Pl. VIII, fig. 3. (Described and discussed as a new species; see below for copy of description. The specimen represented by fig. 3 is redrawn below, fig. 19.)

Mickwitzia? major (Matthew), MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, p. 23. (Discussed in German.)

FIGURE 19.—*Rustella? major* (Matthew). A, A', Cast from a natural mold in sandstone; side outline restored. From Locality 301v, Lower Cambrian shales on Hanford Brook, New Brunswick. The original mold is in the collections of the University of Toronto. The cast from which the figure was drawn is in the collections of the U. S. National Museum, Cat. No. 51462. This specimen was figured by Matthew [1890, Pl. VIII, fig. 3].

The original description by Matthew follows:

Only the dorsal valve known. This is transversely oval, flattened near the umbo, and deep within the edges toward the back of the shell.

The interior markings seem those of an *Obolus*. The median line is strongly marked just within the umbo, and at the middle of the shell, in front of which it appears to fork. The scars of the posterior laterals only are distinct.

The example known shows the interior of the shell and a little of the external surface. The shell was thin, and is changed to iron oxide. The outer surface near the edge of the shell was covered by fine radiating lines or ridges.

Observations.—The type and only specimen of this form is preserved as a natural mold in an impure sandstone; the original shell had been removed, and the resulting mold is very similar to those of *Rustella edsoni* (Pl. I, figs. 1 and 1a) from a fine-grained sandstone; in the case of the latter species only a film remains to indicate the original shell, while in the calcareous nodules embedded in the sandstone the shell is shown to be of considerable thickness.

The reference to the genus *Rustella* is based on the similarity in size and form between this species and *Rustella edsoni* and the fact that *Rustella? major* occurs at about the same stratigraphic horizon in the Lower Cambrian as *R. edsoni* and below the recognized Middle Cambrian fauna. At the same locality and at about the same horizon I found several Lower Cambrian fossils: *Micromitra (Paterina) labradorica*, *Hyalithes cf. communis*, *Coleoloides cf. typicalis* [Walcott, 1900, p. 322].

FORMATION AND LOCALITY.—Lower Cambrian: (301v [Matthew, 1890, p. 155]) Sandy shales of Division 2b of the "Basal series" of Matthew, on Hanford Brook, St. John County, New Brunswick, Canada.

^a The type locality is in italics; where there is but one locality, however, this will not be italicized. When a locality is not represented in the collections of the United States National Museum, the authority for its citation is given immediately after the locality number, or at the end of the paragraph, if several can be grouped under the one reference.

Family PATERINIDÆ Schuchert.

Genus MICKWITZIA Schmidt.^a

- Mickwitzia* SCHMIDT, 1888, Mém. Acad. imp. sci. St.-Pétersbourg, 7th ser., vol. 36, No. 2, p. 24. (Described in German as a new genus.)
- Mickwitzia* Schmidt, HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York for 1891, p. 246. (Described.)
- Mickwitzia* Schmidt, HALL and CLARKE, 1892, Forty-fifth Ann. Rept. New York State Museum for 1891, p. 562. (Copy of preceding reference.)
- Mickwitzia* Schmidt, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, pp. 86-87. (Described and discussed.)
- Causea* WIMAN, 1902, Bull. Geol. Inst. Univ. Upsala, vol. 6, pt. 1, No. 11, pp. 53-54. (Described and discussed in German as a new genus, the description being incorporated with that of the type species, *Causea formosa*.)
- Mickwitzia* Schmidt, WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of genus.)

Shell large, unequivale. Ovate or subcircular, with apex of valves within the margin and erect, or curved over the margin. A false cardinal area may or may not be obscurely defined; valves not articulated. Shell substance mostly calcium phosphate and arranged in three principal layers. The outer layer is papillose, with fine and large punctæ; middle layer marked by numerous radiating and concentric, more or less elevated lines and small punctæ that become very numerous toward the front margins of the shell; inner layer marked by large punctæ or vertical canals and often a thickening of shell substance that takes the form of irregular serpentine ridges penetrated by vertical canals.

Type.—*Lingula? monilifera* Linnarsson.

Observations.—Both Schmidt [1888, p. 24] and Hall and Clarke [1892c, pp. 86-87] define and discuss this genus, but with the new material I have for study, a new diagnosis has been prepared. The genus appears to fall within the order Atremata Beecher [1891, p. 354] and the family Paterinidæ Schuchert [1897, p. 119]. The latter family has heretofore included only the genus *Micromitra*. The species of *Mickwitzia* include chitinous or phosphatic shells with elevated ventral valve, having an apex elevated within the margin (*Mickwitzia formosa* (Wiman)), or arching over the margin (*Mickwitzia monilifera* (Linnarsson)). *Micromitra* has a clearly marked area and pseudodeltidium, in this respect being further advanced in evolution than *Mickwitzia*. A series of shells of *Mickwitzia* might show a more strongly marked false area in the young shell than in the adult forms.

The generic name was given in honor of Dr. A. Mickwitz.

MICKWITZIA FORMOSA (Wiman).

Plate VI, figures 3, 3a-c.

Causea formosa WIMAN, 1902, Bull. Geol. Inst. Univ. Upsala, vol. 6, pt. 1, No. 11, pp. 53-54, Pl. II, figs. 1-5. (Described and discussed in German as a new species. The specimen represented by figs. 1-5 is redrawn in this monograph, Pl. VI, figs. 3, 3a-c.)

Outline of ventral valve circular; apex a little in front of the posterior margin, strongly elevated, and rising vertically above a broad, obscurely defined false area. The area is defined by a rounded angle where the transverse, slightly convex posterior surface below the apex unites with the lateral slopes from the apex. The posterior margin is slightly arched, so as to form an opening between it and the dorsal valve.

Only the inner layers of the shell are preserved on the type specimen, the outer epidermal layer having been exfoliated. On the posterior portion of the shell the second or middle layer has the radiating and concentric lines typical of *Mickwitzia monilifera* (Linnarsson). Toward the front the layer of shell is marked by faint radiating lines and many fine punctæ, exactly as in specimens of *M. monilifera*, where the outer layer is exfoliated. This type of surface is

^a Prior to the definition of *Mickwitzia* by Schmidt [1888, p. 24], the species now referred to this genus were placed under the following genera:
Lingula Linnarsson [1869a, p. 344; 1869b, p. 398]. *Obolus* Linnarsson [1871, pp. 9-10].

shown by Plate VI, figure 1k, except that the punctæ are very few on the center of the shell, which is the part enlarged by the figure. The inner layer of shell of *M. formosa* has numerous large punctæ that penetrate it, and also the irregular serpentine ridged shell deposits characteristic of this species and of many adult shells of *M. monilifera*.

Observations.—Wiman [1902, p. 53] created the genus *Causea* to receive this species. He very kindly sent me the type material for study, and with it a fine collection of *M. monilifera* (Linnarsson). I am unable to determine generic distinctions between the two species. The shell substance and structure are the same, so far as material exists for comparison. *Mickwitzia formosa* has a more elevated apex and is a much larger shell, but these are specific rather than generic distinctions.

FORMATION AND LOCALITY.—Middle? Cambrian: (3111 [Wiman, 1902, p. 57]) Drift boulder of bluish calcareous sandstone, No. 31, on Biludden, about 20 miles (32.2 km.) east of Gefle, Province of Gefleborg, Sweden.

(311s [Wiman, 1902, p. 57]) Drift boulder of gray quartzitic sandstone, at Skarpnätö, Åland Island, Finland, Russia.

MICKWITZIA MONILIFERA (Linnarsson).

Plate VI, figures 1, 1a-p; Plate LIX, figure 2.

Lingula? monilifera LINNARSSON, 1869, Öfversigt af K. svensk. Vet.-Akad. Förhandl. for 1869, Bd. 26, No. 3, p. 344, Pl. VII, figs. 1 and 2. (Described and discussed in Swedish as a new species.)

Lingula monilifera LINNARSSON, 1869, Geol. Mag., vol. 6, p. 398, Pl. XI, figs. 1 and 2. (Text translated into English from Linnarsson, 1869a, p. 344. Figs. 1 and 2 are copied from Linnarsson, 1869a, Pl. VII, figs. 1 and 2.)

Obolus? monilifer LINNARSSON, 1871, Bihang till K. svensk. Vet.-Akad. Handl., Bd. 9, No. 7, pp. 9-10, Pl. I, figs. 2 and 3. (Described and discussed in Swedish.)

Mickwitzia monilifera (Linnarsson), SCHMIDT, 1888, Mém. Acad. imp. sci. St.-Pétersbourg, 7th ser., vol. 36, No. 2, pp. 21-23 and 24-25, Pl. II, figs. 6-26. (Described and discussed in German. Figs. 12c and 12d are copied in this monograph, Pl. VI, figs. 1p and 1o, respectively.)

Mickwitzia monilifera (Linnarsson), WALCOTT, 1891, Tenth Ann. Rept. U. S. Geol. Survey, Pl. LXX, figs. 2, 2a-h. (No text reference. Figs. 2, 2a-f are copied from Schmidt, 1888, Pl. II, figs. 16a, 16c, 16b, 12b, 12c, 12d, and 12a, respectively. Fig. 2h is copied from Linnarsson, 1871, Pl. I, fig. 2.)

Mickwitzia monilifera (Linnarsson), HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York for 1891, figs. 253-255, p. 246. (No text references. Figs. 253-255 are copied from Schmidt, 1888, Pl. II, figs. 14a, 8b, and 16b, respectively.)

Mickwitzia monilifera (Linnarsson), HALL and CLARKE, 1892, Forty-fifth Ann. Rept. New York State Museum for 1891, figs. 253-255, p. 562. (Copy of preceding reference.)

Mickwitzia monilifera (Linnarsson), HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 86, figs. 42-44. (No text reference. Figs. 42-44 are copied from Schmidt, 1888, Pl. II, figs. 14a, 8b, and 16b, respectively.)

Mickwitzia monilifera (Linnarsson), WIMAN, 1902, Bull. Geol. Inst. Univ. Upsala, vol. 6, pt. 1, No. 11, p. 53, Pl. II, figs. 12-14, Pl. IV, figs. 2 and 3. (Characterized and discussed in German.)

General form ovate to subcircular; biconvex or subplanoconvex.

Surface of exterior of the shell papillose; each papilla is about as high as the width of its base, and the apex is perforated by a minute tube. There appears to be no systematic arrangement of the papillæ; they are thickly set over the entire surface of a dorsal valve 20 mm. in diameter; on some parts of the shell the papillæ are closely arranged in undulating, irregular ridges; these, when worn by attrition, have the appearance shown by Plate VI, figure 1m. This outer surface is rarely preserved, as it usually adheres to the matrix, leaving the second layer exposed to view. The layer of shell immediately beneath the outer shell is marked by concentric, elevated, minutely undulating, raised, closely set lines that are crossed by fine, radiating, closely set raised lines (Pl. VI, figs. 1k and 1l); this is the surface illustrated by Linnarsson [1869b, Pl. XI, fig. 2] and Schmidt [1888, Pl. II, fig. 21]; it is seen on most specimens preserving the shell. The distance from the apex, condition of preservation, etc., cause great variation in the appearance of the inner layer. Scattered punctæ penetrate the inner layer, and often the depressions between the concentric and radiating raised lines give the surface a finely and regularly pitted or punctate appearance. On some shells the punctæ are numerous and regularly arranged toward the front of the shell. The inner surface of the inner layer of the shell is marked by strong punctæ in adult shells. Frequently a shell deposit is found over the inner

surface which is punctate and curiously ridged, very much like the outer surface in partly worn shells. (See Pl. VI, fig. 1m, of the outer surface.)

Substance of shell mostly calcium phosphate [Schmidt, 1888, p. 23]. The shell is thick in small shells, but does not increase proportionately in thickness with age.

The largest shell in the collection before me has a length of 32 mm., exclusive of extension of apex over area; width 30 mm.

Ventral valve convex, with apex projecting a little over the posterior margin. A false area is more or less definitely outlined; in some specimens it is quite clear and in others very indefinite; it is much like some of the less clearly defined false areas of species of *Micromitra*. When well defined the posterior margin of the valve arches slightly, as in Plate VI, figure 1e.

Dorsal valve slightly convex, with a very low submarginal apex. The interior of the valve is usually without traces of muscular or vascular markings. In one worn shell a median sinus occurs, and what appears to be the path of advance of the anterolateral muscle scars (Pl. VI, fig. 1f); another unworn shell shows a trace of radiating lines near the median line; and a third has two plainly marked muscle scars a little in advance of the apex and some distance from the median line; these occupy the position of the posterior muscle scars as they occur in the dorsal valve of *Schizocrania*.

Observations.—The preceding description is based on specimens in the collection of the United States National Museum. Mr. Schmalensee, a collector in the Geological Survey of Sweden, at my request collected a number of fine specimens for the United States National Museum. The museum has also received a number of casts from other sources.

Schmidt [1888, p. 22] describes a hooked process as occurring in a cast of a dorsal valve. After noting his expression of doubt as to whether the process belonged to the shell, and also after a study of the interiors of finely preserved dorsal valves, I can not retain the view that such a process exists in the dorsal valve of this species. We may attribute the apparent occurrence of it in the cast studied by Schmidt to the accidental attachment of some foreign body, or it may be that the cast belongs to some other genus and species.

There is no other species of the genus that is closely related to *Mickwitzia monilifera*; *M. formosa* has the same general character of shell, but its ventral valve is more erect, much larger, and it differs a little in the details of the surfaces of the interior layers of the shell.

FORMATION AND LOCALITY.—**Middle? Cambrian:** (311l [Wiman, 1902, p. 57]) Drift bowlder of bluish calcareous sandstone, No. 31, on Biludden, about 20 miles (32.2 km.) east of Gefle, Province of Gefleborg; and (311u [Wiman, 1902, p. 57]) drift bowlder of blue calcareous sandstone, Söderarm lighthouse, near Norrtelje, Province of Stockholm; both in Sweden.

(311e) Drift bowlder of rusty sandstone, south of Lumparn, parish of Jomala; (311f) drift bowlder of gray quartzitic sandstone, at Slemmern, Mariehamn; (311g) drift bowlder of gray quartzitic sandstone, at Ytternäset, Mariehamn; and (311r) drift bowlder of gray quartzitic sandstone, at Granboda, Lemland; all [Wiman, 1902, p. 57] on Åland Island, Finland, Russia.

Lower Cambrian: (390j) *Eophyton* sandstone at Lugnås, 8 miles (12 km.) south-southwest of Mariestad, Province of Skaraborg; and (390k) *Eophyton* sandstone at Prestorp, north of the hill of Billingen, Province of Skaraborg; both in Sweden.

(396q) Upper boundary of the blue clay with the Fucoid sandstone, the "*Mickwitzia* conglomerate" at Reval; (396r) in the "upper strata" at Streitberg, near Reval; (396s) in loose blocks on Kosch Brook near Likkat, near Reval; (396t) at the sandstone capes of Ziegelskoppel, Kakkomaggi (also Rocca al Mare), near Reval; (396u) in loose blocks on the lower course of Jaggowal Brook, about 20 miles (32.2 km.) east-southeast of Reval; (396v) at the upper boundary of a dolomitic sandstone with which the *Olenellus* stratum begins, below the cement factory on Kunda Brook;^a and (396w) in the glauconitic sands above the main mass of the clay, below the cement factory on Kunda Brook; all [Schmidt, 1888, p. 24] in the Government of Esthonia, Russia.

MICKWITZIA OCCIDENS Walcott.

Plate VI, figure 4.

Mickwitzia occidens WALCOTT, 1908, Smithsonian Misc. Coll., vol. 8, No. 3, p. 54, Pl. VII, fig. 1. (Described as below as a new species. Fig. 1 is copied in this monograph, Pl. VI, fig. 4.)

Only crushed and broken specimens of this shell are available. One of these shows that the apex of the ventral valve was a little above the posterior margin of the shell, very much as

^a Specimens of this species from the locality on Kunda Brook are included in the collections of the United States National Museum.

in *Mickwitzia pretiosa* Walcott. The outline of the valves appears to have been ovate to sub-circular and the ventral valve moderately convex. The shell is phosphatic or chitinous and built up of three principal layers. The outer layer is thin, and thickly set with minute pustules or granules that give the surface a roughened appearance. When the outer layer is exfoliated, which is usually the case, the middle layer presents a smooth, shining surface that is marked by a few concentric striæ and numerous fine radiating striæ, between which many minute punctæ occur. The inner layer shows minute, irregular, serpentine, rounded ridges, perforated by vertical canals or punctæ. An interior of a ventral valve shows the lines of advance of the anterolateral muscle scars. The largest shell indicated on the surface of the siliceous shale has a length and width of 12 mm.

The generic reference of this species is based on the apex of the ventral valve and the structure and character of the shell.

FORMATION AND LOCALITY.—**Lower Cambrian:** (53) Sandstones in the lower portion of 3d of the Waucoba Springs section [Walcott, 1908f, pp. 187 and 188], 1 mile (1.6 km.) east of the Saline Valley road, about 2.5 miles (4 km.) east-northeast of Waucoba Springs, Inyo County, California.

(174c) Sandstones on small hill in the salt flat, 1 mile (1.6 km.) northeast of Silver Peak Mill, Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County, Nevada.

MICKWITZIA PRETIOSA Walcott.

Plate VI, figure 2.

Mickwitzia pretiosa WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 54-55, Pl. VII, fig. 2. (Described and discussed as below as a new species. Fig. 2 is copied in this monograph, Pl. VI, fig. 2.)

This species is founded on a single specimen of a ventral valve. It has a length of 7 mm., width 6.5 mm. Outline subcircular, slightly convex; apex curved over toward the posterior margin and projecting beyond it. False area short and obscure. Surface marked by radiating raised lines that at the front margin show six in a distance of 2 millimeters. Fine papillæ are thickly scattered over the surface, with a tendency to follow concentric lines of growth on some portions of the shell, and on others they appear on low, narrow, serpentine ridges, as in *M. monilifera* (Linnarsson). A few large punctæ are scattered here and there over the surface. Inner surfaces and layers of shell unknown.

This beautiful shell differs in the details of its surface from *M. monilifera*; it is also less convex, and the apex is nearer the posterior margin.

FORMATION AND LOCALITY.—**Lower Cambrian:** (390j) *Eophyton* sandstone at Lugnås, 8 miles (12.8 km.) south-southwest of Mariestad, Province of Skaråborg, Sweden.

MICKWITZIA? sp. undt.

Lingula hawkei? BORNEMANN [not ROUAULT], 1891, Nova Acta Acad. Cæs. Leop.-Carol. Germanicæ Naturæ Curiosorum, Bd. 56, No. 3, p. 439, Pl. XIX, figs. 19-20. (Characterized and discussed in German.)

Bornemann describes and illustrates some large shells 3 centimeters or more in diameter from the *Olenopsis* beds, which he states are characterized by a somewhat quadrangular outline and faint sinus and resemble Barrande's "*Lingula feistmanteli*." I am inclined to compare this form with the large compressed casts of *Mickwitzia monilifera* and to make a tentative reference to the genus *Mickwitzia*. The shell is certainly not *Lingula rouaulti* Salter.

FORMATION AND LOCALITY.—**Middle? Cambrian:** (354a [Bornemann, 1891, p. 439]) in grayish-white quartzitic sandstones in the valley of Gutturu Sartu, island of Sardinia, Italy.

Genus MICROMITRA Meek.^a

[μικρός, small; and mitra, a hat.]

Not *Iphidea* BALY, 1865, Entom. Monthly Magazine, vol. 2, p. 127. (Proposed for a genus of Coleoptera.)

Iphidea BILLINGS [not BALY], 1872, Canadian Naturalist, 2d ser., vol. 6, No. 4, pp. 477-478. (Type species ("*Iphidea bella*") described and discussed and "*Iphidea*" mentioned as a new genus. The reference is copied in this monograph under *Micromitra (Paterina) bella*, p. 345.)

^a The synonymy for this genus does not give a complete record of the various genera under which the species now included in *Micromitra* were formerly placed; it includes only those references in which the genus is discussed or described. For the sake of completing the record the remaining mere generic references are here listed:

Kutorgina Linnarsson [1876, p. 25].
Kutorgina Hall and Whitfield [1877, p. 207].
Kutorgina Walcott [1884b, p. 20].

Kutorgina Matley [1902, p. 146].
Kutorgina Grönwall [1902, p. 40].

- Micromitra* MEEK, 1873, Sixth Ann. Rept. U. S. Geol. and Geog. Survey Terr. for 1872, p. 479. (Suggests *Micromitra* as a new generic name for "*Iphidea* (?) *sculptilis*" if that species should prove to belong to a new genus. This reference is quoted in this monograph, p. 334.)
- Iphidea* BILLINGS, 1874, Geol. Survey Canada, Paleozoic Fossils, vol. 2, pt. 1, p. 76. (Copied from Billings, 1872b, pp. 477-478.)
- Iphidea* Billings, LINNARSSON, 1876, Bihang till K. svensk. Vet.-Akad. Handl., Bd. 3, No. 12, p. 26. (Mentioned in English in the discussion of "*Iphidea ornatella*.")
- Iphidea* Billings, DALL, 1877, Bull. U. S. Nat. Mus., No. 8, p. 39. (Mentioned.)
- Iphidea* Billings, WALCOTT, 1886, Bull. U. S. Geol. Survey No. 30, pp. 100-101. (Copies the original description, Billings, 1872b, pp. 477-478, of the type species ("*Iphidea bella*") and discusses genus.)
- Kutorgina* WALCOTT (in part), [not BILLINGS], 1886, Idem, pp. 101-102. (Genus *Kutorgina* described, but description also includes reference to specimens now referred to *Micromitra*, *Micromitra* (*Paterina*), and *Micromitra* (*Iphidella*)).
- Iphidea* Billings, OEHLERT, 1887, Manuel de conchyliologie, by Fischer, p. 1270. (Described in French.)
- ?*Iphidea* Billings, HALL and CLARKE (in part), 1892, Eleventh Ann. Rept. State Geologist New York for 1891, p. 249 (Described, but accompanied by figures of specimens belonging with the subgenus *Paterina*.)
- ?*Iphidea* Billings, HALL and CLARKE (in part), 1892, Forty-fifth Ann. Rept. New York State Mus. for 1891, p. 565 (Copy of preceding reference.)
- Kutorgina* Walcott, HALL and CLARKE (in part), 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, pp. 90-94 (Copies Walcott's description, 1886b, pp. 101-102, and discusses genus, but description and discussion also include reference to specimens now referred to *Micromitra*, *Micromitra* (*Paterina*), *Micromitra* (*Iphidella*), *Prothoris*, and *Billingsella*.)
- Iphidea* Billings, HALL and CLARKE, 1892, idem, pp. 97-98. (Copies the original description, Billings, 1872b, pp. 477-478, of the type species ("*Iphidea bella*") and discusses genus.)
- Iphidea* Billings, WALCOTT (in part), 1897, Proc. U. S. Nat. Mus., vol. 19, pp. 707-711. (Discussed. The genus includes species now referred to *Micromitra*, *Micromitra* (*Paterina*), and *Micromitra* (*Iphidella*)).
- Iphidea* Billings, SCHUCHERT (in part), 1897, Bull. U. S. Geol. Survey No. 87, p. 233. (Merely refers *Micromitra* and *Paterina* to *Iphidea*.)
- Iphidea* Billings, WALCOTT, 1899, Mon. U. S. Geol. Survey, vol. 32, pt. 2, pp. 447-448. (Mentioned in discussion of "*Iphidea sculptilis*.")
- Iphidella* WALCOTT (in part), 1905, Proc. U. S. Nat. Mus., vol. 28, p. 304. (Merely proposed to replace *Iphidea*, but includes reference to specimens belonging with *Micromitra*, *Micromitra* (*Paterina*), and *Micromitra* (*Iphidella*)).
- Paterina* (*Micromitra*) (Meek), SCHUCHERT, 1905, Am. Jour. Sci., 4th ser., vol. 19, p. 329. (Suggests that *Micromitra* be used in a subgeneric sense, under *Paterina*, for the forms typified by *Micromitra sculptilis*.)
- Not *Iphidea* GRABAU and SHIMER, 1907, North American Index Fossils, vol. 1, p. 201. (Described, but the species placed under it belong with the subgenera *Paterina* and *Iphidella*.)
- Micromitra* Meek, WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of genus.)

Ventral valve conical (*Micromitra* (*Paterina*) *etheridgei* (Tate), Pl. III, fig. 10) to depressed conical (*M. (P.) labradorica* (Billings), Pl. II, fig. 2), with the beak curving more or less over a false area which is divided midway by a triangular fissure that may be covered almost entirely (*M. (P.) superba* (Walcott), Pl. II, fig. 1) or only in part (*Micromitra* (*Iphidella*) *ornatella* (Linnarsson), Pl. III, fig. 6) by a convex pseudodeltidium.

Dorsal valve slightly to moderately convex. Beak small and usually curved a little over a low area (*Micromitra pealei* (Walcott), Pl. III, fig. 3e') that has a rather broad pseudodeltidium.

Surface marked by concentric lines of growth and fine radiating striæ (*Micromitra* (*Paterina*) *labradorica* (Billings)); crenulated concentric striæ that give a more or less distinctly crenulated appearance to the surface (*Micromitra sculptilis* (Meek)); and strongly crenulated concentric striæ forming a network of raised, obliquely arranged lines that divide the surface into minute pits (*Micromitra* (*Iphidella*) *pannula* (White)).

Shell substance corneous. Shell built up of thin layers or lamellæ that are more or less oblique to the outer surface.

Very little is known of the interior of the valves. The ventral valve of *Micromitra* (*Paterina*) *labradorica* (Billings) (Pl. II, fig. 2c) has a few lines or ridges that radiate from the beak very much as in *Kutorgina* (Pl. V, fig. 1). The dorsal valve also shows radiating ridges (*Micromitra* (*Iphidella*) *ornatella* (Linnarsson) Pl. III, fig. 6d), and in addition an exfoliated shell of *M. (I.) pannula ophirensis* Walcott shows a median ridge, the base of the main vascular sinuses, and two central muscle scars (Pl. IV, fig. 4e).

Type.—*Iphidea* (?) *sculptilis* Meek [1873, p. 479].

Meek's original reference to *Micromitra* [1873, p. 479] is as follows:

It is quite probable that when specimens showing clearly all the characters of this shell can be examined it will be found to belong to an undefined genus, either of the Brachiopoda or some other group. In this case I would propose for this genus the name *Micromitra*.

The type specimen labeled by Meek in 1873 as *Iphidea* (*Micromitra*) *sculptilis* is in the collections of the United States National Museum (Catalogue No. 7864). The label is in Meek's handwriting and firmly attached to the specimen of rock containing the shell.

The description of the shell referred to *Iphidea* (??) *sculptilis* Meek [1873, p. 479] is that of the ventral valve. While no generic description is given and the specific description is incomplete, we are necessitated by the present rules of nomenclature to accept the name *Micromitra*, since *Iphidea*, as proposed by Billings [1872b, p. 477], was preoccupied by Baly in 1865.

When away, engaged in field work, I accidentally discovered that the genus *Iphidea* was first used by Baly in 1865. I then put the name *Iphidella* in some manuscript notes and by oversight this name was published [Walcott, 1905a, p. 304]. Schuchert [1905, p. 329] called attention to its being a synonym of *Micromitra* and *Paterina*. This is shown in my synonymy of the genus *Iphidea* [1897b, p. 707]. I now use *Iphidella* as a subgenus of *Micromitra*.

Billings's description of the genus *Iphidea* and that of the type species were combined. At the time of my study of *Kutorgina* and *Iphidea* [Walcott, 1886b, p. 100] I did not agree with Billings in his reference of "*Obolus labradoricus*" to *Iphidea* [Billings, 1874, p. 76]. Since that time I have collected more material representing this group of shells, and from its study have come to the conclusion that Billings was correct in referring "*O. labradoricus*" to his genus *Iphidea*. The ventral valve of "*O. labradoricus*" has a narrow false area of the same type as *Micromitra* (*Paterina*) *bella* (Billings), and the characteristic pseudodeltidium is clearly shown in a section, and it is known to occur in *Micromitra sculptilis* (Meek), *Micromitra* (*Iphidella*) *ornatella* (Linnarsson), and *M. (I.) pannula* (White). The extreme development of the false area and pseudodeltidium is found in *M. (P.) superba* (Walcott), from the Middle Cambrian "Tonto" sandstone of the Grand Canyon of the Colorado. In this form the ventral valve is broadly conical, and the large pseudodeltidium projects backward at an angle equal to the slope from the apex to the front. In *Micromitra* (*Paterina*) *bella* the false area slopes more abruptly downward and in *Micromitra* (*Iphidella*) *ornatella* it is nearly vertical, the pseudodeltidium being much shorter and projecting but a short distance beyond the area. The slope of the area of *M. (I.) ornatella* is essentially the same as that of *Micromitra* (*Paterina*) *labradorica swantonensis* (Walcott), which is the type of Beecher's genus *Paterina*. (See p. 344.) In some specimens of the latter species the beak projects so that the slope of the area carries it forward to a considerable distance under the beak. This is also true of *Micromitra* (*Iphidella*) *pannula*.

The presence of an apical foramen in *Micromitra* (*Paterina*) *bella* and *Micromitra* (*Iphidella*) *ornatella* would separate those species from the Paterinidæ, but from a careful study of all the evidence attainable I am led to question the presence of a true apical foramen in either species. Unless there are other characters than those shown by the false area and pseudodeltidium and the angle at which they slope, it will be impracticable to generically separate *Micromitra* (*Paterina*) *bella* and *M. (P.) labradorica* and the other species mentioned.

In his original description, Billings [1872b, p. 478] says:

In the specimen above figured there is an aperture in the beak, but in another there is no appearance whatever of a perforation.

In a fine series of *Micromitra* (*Paterina*) *bella* from the Lower Cambrian, south of Emigsville, York County, Pennsylvania, the characteristics of the genus and species are strikingly well shown. In none of the specimens is there in the ventral valve an indication of an apical pedicle opening. The dorsal valve is slightly elevated, and in the half-dozen well-preserved specimens no trace has been observed of any false area or pseudodeltidium; but in *Micromitra* (*Iphidella*) *pannula* the false area is even more clearly defined than in the ventral valve, and the pseudodeltidium is present as a depressed concave covering of more than one-half of the triangular space inside the narrow area on each side. The area on the dorsal valve has also been observed in *M. (I.) ornatella* (Linnarsson) and *Micromitra* (*Paterina*) *labradorica* (Billings).

Linnarsson [1876, p. 25], in describing *Micromitra* (*Iphidella*) *ornatella*, speaks of the presence of a minute foramen; but, after the study of several finely preserved ventral valves from the *Paradoxides* beds of Andrarum, Sweden, I am led to believe that what he considered to be an apical foramen is a depression in the apex of the shell on the incurved beak which was present in one of the embryonic (nepionic) stages and was subsequently lost. This would involve the crowding out, as it were, of the pedicle posteriorly, the only evidence of its presence in the adult being the narrow, slightly depressed slit at the apex of the valve in some specimens. The pedicle in the adult shell is protruded between the two valves and separated from the scar of the embryonic pedicle slit by the growth of a pseudodeltidium.

The examination of the somewhat closely allied form, *Micromitra* (*Iphidella*) *pannula* (White), shows the presence in some specimens of an apical depression, and its absence in others. In *Micromitra* (*Paterina*) *superba* (Walcott), still more closely approaching the type, *M. (P.) bella* (Billings), in external appearance, there is no trace of an apical slit. In *Micromitra* (*Paterina*) *erenistria* (Walcott), which is associated with *M. (P.) superba*, the apex is rounded, while in the somewhat similar but distinct form, *M. pealei* (Walcott), from the Gallatin River valley of Montana, the apical slit is as clearly shown as in *Micromitra* (*Iphidella*) *ornatella* (Linnarsson), but there is no apical foramen.

Hall and Clarke [1892c, p. 97] illustrate a specimen of *Micromitra* (*Paterina*) *bella* showing an apical foramen, but in the description of Pl. IV, fig. 8, the statement is made that the foramen is not altogether distinct in the specimen.

The systematic position of the genus *Micromitra* appears to be in the Atremata of Beecher [1891, p. 354], with possible characters that nearly place it in the Protremata. The presence of an obscure apical furrow in front of the apex of *Micromitra* (*Paterina*) *bella* (Billings), *Micromitra* (*Iphidella*) *ornatella* (Linnarsson), and in some specimens of *Micromitra* *pealei* (Walcott) tends to support the view that the pedicle was apical in its early stages. We also have to consider the area of what appears to be the dorsal valve of *Micromitra* (*Iphidella*) *pannula*. In this species there is a rather deep convex pseudodeltidium in the conical valve and a clearly defined, depressed pseudodeltidium on the flat valve between the sides of the narrow false area. There is also present on the latter valve a narrow median groove extending from the apex to the posterior margin of the pseudodeltidium; it is similar in appearance to the pedicle groove of the ventral valve of *Obolus* and *Rhinobolus*. This suggests that the flat valve may be the pedicle valve, but the presence of a scar of the embryo pedicle opening on the conical valve is opposed to such an interpretation.

It may be urged that *Micromitra* is a true atrematous genus, the pedicle never having been inclosed and the slit on the ventral valve being only a depression without special significance. This may be so, but the impression it conveys to me is that the slit indicates a pedicle opening which existed near the apex of the ventral valve at an early stage in its growth, but which was subsequently closed, the pedicle continuing to protrude between the valves.

Whiteaves wrote me, under date of July 23, 1896, that with the exception of the specimen which is referred in this monograph to *Micromitra* (*Paterina*) *logani* (see pp. 345 and 350), there were no specimens or electrotypes of the types of *Micromitra* (*Paterina*) *bella* (Billings) in the collections of the Geological Survey of Canada, nor of the closely allied species of the same genus from Topsail Head, mentioned by Billings [1872b, p. 478]. Under the circumstances nothing can be done but to decide from Billings's description and figure [1872b, p. 477] the characters of the species, and refer to the species the form that can best be identified with the description and figure as its typical representative. This appears to be the form from the Lower Cambrian limestone of York County, Pennsylvania. (See pp. 345 and 350, and Pl. II, figs. 1 and 1c.)

Ornamentation of the surface.—One of the most noticeable characters is the surface ornamentation. The type species of *Micromitra* (*M. sculptilis* (Meek), Pl. III, figs. 5, 5a-c) has on some specimens (Pl. III, figs. 5c, 5d) concentric lines similar to those on the less ornamented forms of the genus, as represented by *Micromitra* (*Paterina*) *labradorica* (Billings), and on other specimens a well-defined series of radiating ridges of varying number, width, and strength (Pl. III, figs. 5, 5a, and 5c). It was on account of the surface produced by the concentric lines crossing the radiating ridges that the specific name *sculptilis* was proposed.

Micromitra sculptilis (Meek), the type of group *A* (*Micromitra* Meek), is therefore intermediate in surface characters between the concentrically striated forms of group *B* (*Paterina* Beecher) and the network ornamentation of group *C* (*Iphidella* Walcott), though some examples of the latter group have both the *A* and *C* types of surface on the same shell. The species with the intermediate type of surface may be grouped under the genus *Micromitra*, as follows:

| | |
|-----------------------------------------------|----------------------------|
| <i>Micromitra alabamaensis</i> (Walcott)..... | Middle Cambrian. |
| <i>haydeni</i> Walcott..... | Do. |
| <i>nisus</i> (Walcott)..... | Do. |
| <i>pealci</i> (Walcott)..... | Do. |
| <i>pusilla</i> (Linnarsson)..... | Do. |
| <i>scotica</i> Walcott..... | Lower Cambrian. |
| <i>sculptilis</i> (Meek)..... | Middle and Upper Cambrian. |
| <i>sculptilis endlichi</i> Walcott..... | Middle Cambrian. |
| <i>zenobia</i> Walcott..... | Do. |

Micromitra (Paterina) labradorica swantonensis (Walcott) and *M. (P.) bella* (Billings) represent the second type (*B*), whose surface is formed of simple concentric striæ and lines of growth. On the basis of surface characters this group is given a subgeneric value, as suggested by Schuchert [1905, p. 329], and the name *Paterina* of Beecher [1891, p. 345] is adopted.^a The group includes:

| | |
|----------------------------------------------------|------------------|
| <i>Micromitra (Paterina) bella</i> (Billings)..... | Lower Cambrian. |
| <i>crenistria</i> (Walcott)..... | Middle Cambrian. |
| <i>etheridgei</i> (Tate)..... | Do. |
| <i>labradorica</i> (Billings)..... | Lower Cambrian. |
| <i>orientalis</i> (Walcott)..... | Do. |
| <i>swantonensis</i> (Walcott)..... | Do. |
| <i>utahensis</i> (Walcott)..... | Middle Cambrian. |
| var. <i>undt</i> | Lower Cambrian. |
| <i>logani</i> (Walcott)..... | Middle Cambrian. |
| <i>major</i> (Walcott)..... | Lower Cambrian. |
| <i>phillipsi</i> (Holl)..... | Upper Cambrian. |
| <i>prospectensis</i> (Walcott)..... | Lower Cambrian. |
| <i>stissingensis</i> (Dwight)..... | Middle Cambrian. |
| <i>stissingensis ora</i> Walcott..... | Do. |
| <i>stuarti</i> Walcott..... | Do. |
| <i>superba</i> (Walcott)..... | Do. |
| <i>undosa</i> (Moberg)..... | Lower Cambrian. |
| <i>wapta</i> Walcott..... | Do. |
| <i>williardi</i> Walcott..... | Do. |

Micromitra (Iphidella) ornatella (Linnarsson) and *M. (I.) pannula* (White) represent the third type (*C*), whose surface is formed by the union of the crenulated striæ so as to form a fine network of raised obliquely arranged lines that divide the surface into minute pits that give the impression of finely woven cloth. For the species with this ornamented surface *Iphidella* Walcott [1905a, p. 304] is used in a subgeneric sense. This includes:

| | |
|---------------------------------------------------|----------------------------|
| <i>Micromitra (Iphidella) louise</i> Walcott..... | Lower Cambrian. |
| <i>nyssa</i> Walcott..... | Middle Cambrian. |
| <i>ornatella</i> (Linnarsson)..... | Do. |
| <i>pannula</i> (White)..... | Lower and Middle Cambrian. |
| <i>maladensis</i> (Walcott)..... | Middle Cambrian. |
| <i>ophirensis</i> (Walcott)..... | Do. |

Stratigraphic distribution.—The genus ranges from low down in the Lower Cambrian through the Middle Cambrian, and there are two species in the Upper Cambrian.

Of the Lower Cambrian species, *M. (I.) pannula* (White) passes up into the central portion of the Middle Cambrian in the Marjum limestone of the House Range section, Utah. *Micromitra sculptilis* (Meek) occurs abundantly in the central portion of the Middle Cambrian and has also been found in the Upper Cambrian Dunderberg shale of the Eureka district, Nevada.

Micromitra (Iphidella) pannula ophirensis (Walcott) has a range of 2,370 feet (722.4 m.) in the House Range section of Utah, occurring in the Middle Cambrian at horizons 220, 2,075, and 2,590 feet (67, 632.5, and 789.4 m.) above the quartzitic sandstones of the Lower Cambrian.

^a It is therefore impossible to use the type of the preoccupied genus *Iphidea*, *Micromitra (Paterina) bella*, as the type of this subgenus, as Beecher founded it on "*Obolus labradoricus*." (See p. 344.)

At Ophir, in the Oquirrh Range, it is at the horizon of the Pioche fauna, or near the base of the Middle Cambrian.

The table in the introduction gives a summary of the numbers and the range of the genus by species and varieties. (See p. 99.)

MICROMITRA ALABAMAENSIS (Walcott).

Plate II, figures 5, 5a-c.

Iphidea alabamaensis WALCOTT, 1897, Proc. U. S. Nat. Mus., vol. 19, pp. 713-714, Pl. LIX, figs. 5, 5a-b. (Discussed somewhat as below as a new species. The specimens represented by figs. 5, 5a-b are redrawn in this monograph Pl. II, figs. 5, 5a, and 5c, respectively.)

In following the Lower Cambrian rocks southward from Vermont, the first type of *Micromitra* met with is *M. stissingensis* (Dwight), which occurs in the Middle Cambrian of Dutchess County, New York. This is fairly well distinguished by its surface character from *Micromitra (Paterina) labradorica* (Billings) and its variety *swantonensis* (Walcott), but at the next locality to the south in eastern Tennessee, 4 miles (6.4 km.) north of Rogersville, in the Rogersville shale of the Middle Cambrian, was found a form that is practically identical with the northern species or its variety, so far as it is possible to compare specimens preserved in limestone with those preserved in shale. A species of the same general form also occurs in the Middle Cambrian shales of the Cowan Creek section, Cherokee County, Alabama. There is, however, a difference in the surface striæ that distinguishes it from *M. (P.) labradorica*, *M. (P.) labradorica swantonensis*, and *M. (P.) stissingensis*. It is the tendency to crenulation of the striæ in nearly all the specimens that have been examined. This, in extreme cases, goes so far as to approach the surface so characteristic of *Micromitra (Iphidella) pannula* (White). The form can not well be identified with the closely related *M. (P.) labradorica* (Billings) or its variety *swantonensis* (Walcott) or *M. (P.) stissingensis* (Dwight) on account of these peculiar surface characters, and the name *M. alabamaensis* was proposed for it.

In the general form of the valves this species resembles *M. (P.) labradorica* and *M. (P.) stissingensis*. So far as known the only specific difference is in the surface character, which allies it with *Micromitra sculptilis* (Meek). The convexity of the valves is unknown, owing to the compression of the shells in the shale, and we have no information of the area or pseudodeltidium. Shell substance corneous.

FORMATION AND LOCALITY.—Upper Cambrian: (94o) Limestone at base of dolomite, 0.25 mile (0.4 km.) beyond Givens Ford, Cowan Creek, about 8 miles (12.8 km.) southeast of Center, Cherokee County, Alabama.

Middle Cambrian: (90x and 94a) In and attached to the outer surface of siliceous nodules in the Conasauga ("Coosa") shale, Coosa Valley, east of Center; (95a) shales on Spring Creek, near the old tram crossing north of Center road, Cowan Creek valley, southeast of Center; and (94) shales 0.25 mile (0.4 km.) beyond Steel Ford, Cowan Creek, about 8 miles (12.8 km.) southeast of Center; all in Cherokee County, Alabama.

(121a) Shales on road leading from southeast of Harlan Knob to Amis post office; (124) shales (Nolichucky?) overlying the limestone which rests on the Rogersville shale, on Big Creek, southeast of Harlan Knob; (123) upper part of Maryville limestone, on Big Creek, southeast of Harlan Knob; and (121) Rogersville shale, road just east of Harlan Knob; all about 4 miles (6.4 km.) northeast of Rogersville [Keith, 1905, p. 4, and areal geology sheet], Hawkins County, Tennessee.

(14a) Sandstone of the Rome formation, along First Creek Gap, 4 miles (6.4 km.) north-northeast of Knoxville [Keith, 1905, areal geology sheet], Knox County, Tennessee.

MICROMITRA HAYDENI Walcott.

Text figures 20A-D, page 338.

Micromitra haydeni WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 55-56, Pl. VII, figs. 3 and 3a. (Described and discussed as below as a new species. Figs. 3 and 3a are copied in this monograph as figs. 20A and 20B'.)

Ventral valve subconical, with a minute beak arching slightly over a strong, arched pseudodeltidium which is about one-half as long as the height of the valve. Cardinal slope rounded; a slight angle is indicated by a line where the concentric surface striæ bend inward toward the pseudodeltidium across the narrow area; a sharp angle is formed where the convex pseudodeltidium rises abruptly from the area.

Dorsal valve moderately convex, most elevated at the small umbo just in advance of the marginal minute beak; area very low and narrow, and without trace of pseudodeltidium so far as now known.

Surface marked by fine, concentric, slightly undulating, threadlike striæ and a varying number of irregular, more or less interrupted, narrow, depressed, rounded radiating ridges; these ridges are usually most numerous at the central portions of the valves. The concentric striæ extend across the narrow area and arch over the pseudodeltidium, where they are finer and crowded together so that all the striæ between the apex and the front margin are compressed in about one-half the distance on the pseudodeltidium. The adult ventral valve is about 4.5 mm. in length by 5 mm. in width and 2.5 mm. in height, with a pseudodeltidium 1.3 mm. in length. A dorsal valve 2 mm. in length has a height of about 0.5 mm. at the umbo. The shell is rather thick for a species of this size, and it is built up of several thin layers or lamellæ.

Observations.—*Micromitra haydeni* differs from the nearest related species, *M. sculptilis* (Meek), in having a strong convex pseudodeltidium, less elevation of the ventral valve, and a thicker shell. *Micromitra haydeni* occurs near the base of the Middle Cambrian and *M. sculptilis* about 2,000 feet (610 m.) higher in the section of the Cambrian rocks of Utah and southern Idaho.

FIGURE 20.—*Micromitra haydeni* Walcott. A, Top view of ventral valve (U. S. Nat. Mus. Cat. No. 51437a). B, B', Side and back views of a ventral valve (U. S. Nat. Mus. Cat. No. 51437b). C, Exterior of dorsal valve (U. S. Nat. Mus. Cat. No. 51437c). D, Dorsal valve (U. S. Nat. Mus. Cat. No. 51437d).

The specimens represented are from Locality 54s, Middle Cambrian limestones, near Malade, Idaho. Figures 20A and 20B' are copied from Walcott [1908d, Pl. VII, figs. 3 and 3a]. Figure 20A represents the type specimen.

The specific name is given in honor of Dr. F. V. Hayden, geologist and explorer, under whose charge the geology of this region was first studied.

FORMATION AND LOCALITY.—Middle Cambrian: (54s) Dark blue-gray Langston limestone [Walcott, 1908f, p. 198], just above the Cambrian quartzitic sandstones, north side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

MICROMITRA NISUS (Walcott).

Plate II, figure 10.

Iphidella nisus WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 305. (Described and discussed as below as a new species.)

Ventral valve rather low, with the apex overhanging the posterior margin. Surface marked by very fine lines of growth with still finer bands of striæ between them. About 10 very fine radiating ridges extend from near the apex to the front and lateral margins.

This little shell is represented by a single specimen of the ventral valve. The associated fauna includes fragments of *Olenellus*.

I was at first inclined to refer this shell to *Micromitra sculptilis* (Meek) or *M. pealei* (Walcott), but the overhanging apex and strongly marked surface and the fact that there is an interval of 2,000 miles between the localities of the species led me to separate them. Stratigraphically the two latter species occur in the Middle Cambrian and *M. nisus* in the Lower Cambrian. I do not think the two forms should be included in one species.

FORMATION AND LOCALITY.—Lower Cambrian: (2r) In a limestone boulder in a conglomerate, in a railroad cut 2 miles (3.2 km.) west of Bic railway station, Rimouski County, Quebec, Canada.

MICROMITRA PEALEI (Walcott).

Plate III, figures 3, 3a-e.

Iphidea pealei WALCOTT, 1897, Proc. U. S. Nat. Mus., vol. 19, pp. 712-713, Pl. LIX, figs. 3, 3a-c. (Described and discussed as below as a new species. The two specimens represented by figs. 3, 3a-b, and 3c are redrawn in this monograph, Pl. III, figs. 3, 3a-h, and 3c, respectively.)

Ventral valve subconical, beak slightly incurving over the pseudodeltidium. Cardinal slope flattened to form a narrow false area, which is clearly defined from the curvature of the shell by a slightly elevated threadlike ridge. Pseudodeltidium comparatively narrow, strongly convex, and arched below. The striæ of growth cross the false area and arch over the delthyrium.

Dorsal valve moderately convex, and without any special characteristics to distinguish it from the same valve in *Micromitra (Paterina) bella* (Billings), *M. (P.) superba* (Walcott), and *M. (P.) labradorica* (Billings).

Surface marked by fine concentric striæ and lines of growth that are usually plain, but in some examples are slightly crenulated. In such instances fine radiating lines or striæ are also shown. Shell substance corneous.

In the most perfectly preserved specimens there is a slight furrow or depression near the apex of the ventral valve, but there is no trace of a perforation or apical opening.

This species approaches *M. sculptilis* (Meek) in some examples of the ventral valve. It differs mainly in the narrow pseudodeltidium and the character of the surface markings. It might be considered as a form intermediate between *M. (P.) bella* (Billings) and *M. sculptilis* (Meek).

The specific name was given in honor of Dr. A. C. Peale, of the Hayden Survey, who collected the type specimen.

FORMATION AND LOCALITY.—**Middle Cambrian:** (4n) Limestone about 325 feet (99.1 m.) above the unconformable base of the Cambrian in divide at the head of Jackson Creek (locally known as Sheep Creek), a creek flowing into Jackson Lake about 0.5 mile (0.8 km.) south of its northwestern corner, Teton Mountains, Grand Teton quadrangle (U. S. Geol. Survey), Uinta County, Wyoming.

(159) Limestones north of West Gallatin (Gallatin) River, Gallatin County; (302) limestone east of Gallatin River, above Gallatin, Gallatin County; (4p) about 225 feet (68.6 m.) above base of Cambrian in limestones interbedded in Flathead shales of Peale [1893, p. 21], on the north side of West Gallatin (Gallatin) River, 2 miles (3.2 km.) north-east of Logan, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County; (155a) limestone north of East Gallatin River, near Hillsdale, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County; (4h) about 375 feet (114.3 m.) above base of Cambrian in limestone interbedded in the Flathead shales of Peale [1893, p. 21], 1 mile (1.6 km.) north of the junction of East Gallatin and West Gallatin (Gallatin) rivers, 4 miles (6.4 km.) east-northeast of Logan, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County; (5f and 340) limestone interbedded in the Wolsey shale [Weed, 1900, p. 285], in Meagher County on road to Wolsey, south of the divide at the head of Sawmill Creek, and about 12 miles (19.3 km.) south of Neihart, Little Belt Mountains quadrangle (U. S. Geol. Survey), Cascade County; (4x) limestone interbedded in the Wolsey shale [Weed, 1900, p. 285], at the base of a butte in Belt Park, about 6 miles (9.6 km.) northwest of Neihart, Little Belt Mountains quadrangle (U. S. Geol. Survey), Cascade County; and (9h) limestone on Beaver Creek, 5 miles (8 km.) north of York, about 8 miles (12.8 km.) north of Canon Ferry, Big Belt Mountains, Fort Logan quadrangle (U. S. Geol. Survey), Meagher County; all in Montana.

(74) Sandstone about 300 feet (91.4 m.) above the base of the Tonto group, at the head of Nunkoweap Valley, Grand Canyon of the Colorado, Arizona.

MICROMITRA PUSILLA (Linnarsson).

Plate III, figures 2, 2a-c.

Kutorgina cingulata pusilla LINNARSSON, 1876, Bihang till K. svensk. Vet.-Akad. Handl., Bd. 3, No. 12, p. 25, Pl. IV, figs. 53 and 54. (Described as below, and discussed in English, as a new variety.)

Kutorgina cingulata WALCOTT (in part) [not BILLINGS], 1886, Bull. U. S. Geol. Survey No. 30, pp. 102-104. (Specimens now referred to *Micromitra pusilla* were included with the specimens representing *Kutorgina cingulata* when this description was written.)

Kutorgina cingulata pusilla LINNARSSON, MATLEY, 1902, Quart. Jour. Geol. Soc. London, vol. 58, pt. 1, pp. 146-147, figs. 19 and 20, p. 147. (Discussed from a new locality.)

Kutorgina cingulata pusilla LINNARSSON, GRÖNWALL, 1902, Danmarks Geol. Undersøgelse, Række 2, No. 13, pp. 40-41. (Discussed in Norwegian.)

Linnarsson [1876, p. 25] gives the following description of the dorsal valve of this species:

Shell small, transversely oval, broadest about the middle. Hinge-line straight, shorter than the width of the shell; cardinal angles rounded. Shell substance apparently corneous. Surface marked with numerous sharply marked, concentric lines of growth. Length, 3 mm.; breadth, 4 mm.

In some material received from Andrarum, Sweden, I found what appear to be the ventral and dorsal valves of this species associated with *Micromitra* (*Iphidella*) *ornatella* (Linnarsson) and *Acrotreta socialis* von Seebach. The ventral valve shows a well-defined false area on each side of a triangular opening. The broken edge of the pseudodeltidium is shown on the side of the upper end of the fissure, but its form and depth can not be determined.

This species is related to *Micromitra* (*Paterina*) *labradorica* (Billings), differing from it in having a less elevated ventral valve, radiating ridges on the surface, and being more uniformly smaller in size. It is evidently a rare form, as only three specimens were met with in breaking up a large quantity of rock.

FORMATION AND LOCALITY.—Middle Cambrian: (8w) Limestones of the *Paradoxides forchhammeri* zone, at Andrarum, 20 miles (32.2 km.) northwest of Simrishamn, Province of Christianstad; (320t) limestone at Andrarum, 20 miles (32.2 km.) northwest of Simrishamn, Province of Christianstad; and (320u [Linnarsson, 1876, p. 25]) strata with *Agnostus laevigatus* at Östra Rynninge, in Nerike; all in Sweden.

(16h) Limestones of the *Paradoxides forchhammeri* zone at Borregaard; and (16j) limestones of the *Paradoxides forchhammeri* zone at Laeså; both on Bornholm Island, Denmark.

Matley [1902, p. 146] has identified this species from the following locality:^a

Upper Cambrian: (304b) Lower part of the "White Leaved Oak" shales (the zone of *Polyphyra*), Malvern Hills, between Herefordshire and Worcestershire, England.

MICROMITRA SCOTICA n. sp.

Text figures 21A-C.

Ventral valve moderately convex, transverse in outline. Beak almost apical, slightly in advance of the posterior margin, which is nearly straight. Cardinal slopes flattened to form a false area that is almost as wide as the greatest width of the shell. Pseudodeltidium narrow and arching somewhat above the plane of the margin of the shell.

Dorsal valves unknown.

Surface marked by rather coarse concentric striae and radiating ridges. The concentric striae cross the false area and the pseudodeltidium.

Observations.—This species appears to be most closely related to *Micromitra pusilla* (Linnarsson), but is to be distinguished from that species by reason of its long pseudodeltidium and the fact that the beak does not overhang the false

area. The latter species occurs in the Middle Cambrian and *Micromitra scotica* is associated with *Olenellus* in Scotland.

FORMATION AND LOCALITY.—Lower Cambrian: (316d)^b Localities M2646c, M2647c, and M4178d of the Geological Survey of Scotland, about 500 feet (152.5 m.) above the provisional base of the Cambrian and 75 feet (23 m.) below what is believed to be the top of the Lower Cambrian in the shales forming 5 and 6 of the section given by Peach and Horne [1907, p. 414], in a small burn on the north slope of Meall á Ghiubhais, 4 miles (6.4 km.) west-northwest of the Kinlochewe Hotel, Loch Maree, Ross-shire, Scotland.

FIGURE 21.—*Micromitra scotica* n. sp. A, Type specimen, a ventral valve, X4, from Locality 316d, Lower Cambrian shale on Meall á Ghiubhais, Ross-shire, Scotland (U. S. Nat. Mus. Cat. No. 58310). B, B', B'', Top, side, and back views of a ventral valve, X5, from Locality 316d, Lower Cambrian shale on Meall á Ghiubhais, Ross-shire, Scotland (Geol. Survey Scotland, specimen No. M2646c). C, Top view of a crushed ventral valve, X2.5, from Locality 316d, on Meall á Ghiubhais, Ross-shire, Scotland (Geol. Survey Scotland, specimen No. M4178d).

^a Groom [1902, p. 109] describes the locality and cites a list of the associated species.

^b Specimens from this locality are also included in the collections of the United States National Museum.

MICROMITRA SCULPTILIS (Meek).

Plate III, figures 5, 5a-e.

Iphidea (?) *sculptilis* MEEK, 1873, Sixth Ann. Rept. U. S. Geol. and Geog. Survey Terr. for 1872, p. 479. (Described and discussed as a new species, and the generic name "*Micromitra*" proposed in case the species should prove to belong to a new genus.)

Kutorgina minutissima HALL and WHITFIELD, 1877, U. S. Geol. Expl. 40th Par., vol. 4, pt. 2, pp. 207-208, Pl. I, figs. 11 and 12. (Described and discussed as a new species. The specimens represented by figs. 11 and 12 are redrawn in this monograph, Pl. III, figs. 5b and 5c, respectively.)

Kutorgina sculptilis (Meek), WALCOTT, 1884, Mon. U. S. Geol. Survey, vol. 8, p. 20, Pl. I, figs. 7, 7a-b, Pl. IX, fig. 7. (The three specimens represented in Pl. I, figs. 7 and 7a, Pl. I, fig. 7b, and Pl. IX, fig. 7, are redrawn in this monograph, Pl. III, figs. 5, 5b, and 5c, respectively.)

Iphidea sculptilis Meek, SCHUCHERT, 1897, Bull. U. S. Geol. Survey No. 87, p. 235. (Merely goes back to original generic reference.)

Iphidea sculptilis Meek, WALCOTT, 1899, Mon. U. S. Geol. Survey, vol. 32, pt. 2, pp. 447-448, Pl. LX, figs. 5, 5a-c. (Discussed. The specimen represented by figs. 5, 5a-c is redrawn in this monograph, Pl. III, fig. 5a.)

Iphidella sculptilis (Meek), WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 308. (Merely changes generic reference.)

In the description of *Iphidea* (?) *sculptilis*, Meek [1873, p. 479] decided that as the shell had a very narrow, slightly flattened margin on each side, representing a false area, and that as there seemed to be a wide-open triangular foramen, it could be referred to the genus *Acrotreta* or the genus *Iphidea*. He was not positive that there was not a permanent pseudodeltidium present, but assuming the absence of that structure, and thinking it probable that when all the characters of the shell were known it would be found to belong to a different genus, either of the Brachiopoda or of some other group, he proposed for the genus the name "*Micromitra*."

A study of the specimens of *M. sculptilis* collected from the same horizon, at a point not far distant from the original locality, shows the presence of a false area and a pseudodeltidium of the same type as that of *Micromitra* (*Paterina*) *bella* (Billings). There is, however, a difference in the two forms that is considered of subgeneric value. The surface of *M. (P.) bella* is covered with fine concentric striæ and the surface of *Micromitra sculptilis* is marked by very fine, sharp, elevated concentric lines that coalesce or bifurcate irregularly, imparting a peculiarly interrupted wavy appearance that is highly characteristic. The variation in the surface character is continued still further in *Micromitra* (*Iphidella*) *pannula* (White), in which the surface is divided into minute porelike pits by a very fine network of oblique raised lines. Under the lens the surface resembles that of finely woven cloth.

The most nearly related species is *Micromitra haydeni* Walcott, which has a similar surface, but the latter has a large pseudodeltidium on the ventral valve, and that valve is more depressed than in *M. sculptilis*.

A fragmentary ventral valve from 2,500 feet (762 m.) up in the Middle Cambrian series of the northern Wasatch Mountains appears to be a form somewhat intermediate between *Micromitra* (*Paterina*) *crenistris* (Walcott) and *M. sculptilis*. It has the surface of the latter except that the radiating ribs are very faint. It occurs in the Blacksmith Fork section, east of Hyrum, Utah.

FORMATION AND LOCALITY.—Upper Cambrian: (61) Limestone in the Dunderberg shale [Walcott, 1908f, p. 184], a little south of the Hamburg mine; and (62) limestone in the Dunderberg shale [Walcott, 1908, p. 184], in a canyon immediately north of Adams Hill; both in the Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

Middle Cambrian: (302) Limestone east of Gallatin River, above Gallatin; and (302a and 302c) limestones at several places on the south side of the Gallatin Valley; both in Gallatin County, Montana.

(302b) Limestones near Crowfoot Ridge, Gallatin quadrangle (U. S. Geol. Survey), Yellowstone National Park, Wyoming.

(55a) About 1,850 feet (564 m.) above the Brigham quartzite and 2,350 feet (716 m.) below the Upper Cambrian in the limestones forming 2g of the Bloomington formation [Walcott, 1908f, p. 195], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

(8i) Shales believed to be referable to the lower portion of the Marjum limestone [Walcott, 1908f, p. 180], found about 0.5 mile (0.8 km.) east of Antelope Springs; (3x) about 2,200 feet (670.6 m.) above the Lower Cambrian and 2,200 feet (670.6 m.) below the Upper Cambrian in the limestones forming 1d of the Marjum limestone [Walcott, 1908f, p. 180], 2.5 miles (4 km.) east of Antelope Springs in ridge east of Wheeler Amphitheater; and (10y) about 2,900

feet (884 m.) above the Lower Cambrian and 1,500 feet (457.2 m.) below the Upper Cambrian in the central part of the bed forming 1a of the Marjum limestone [Walcott, 1908f, p. 179], about one mile (1.6 km.) south-southwest of Marjum Pass; all in the House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.

(11s) Shales just above Simpson Spring, about 20 miles (32.2 km.) west-southwest of Vernon, on the stage road from Vernon to Fish Spring, Tooele County, Utah.

(10w) Shaly limestones about 5 miles (8 km.) northeast of Osceola, on the east side of the Snake Range, White Pine County; and (58) shaly limestones in upper beds of Secret Canyon shale, either in New York or Secret Canyon, Eureka district [Hague, 1892, Atlas], Eureka County; both in Nevada.

Specimens that are compared with *Micromitra sculptilis* occur at the following locality:

Middle Cambrian: (54i) About 2,950 feet (899.2 m.) above the Brigham quartzite and 1,225 feet (373.4 m.) below the Upper Cambrian in the limestone forming 1e of the Bloomington formation [Walcott, 1908f, p. 194], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

MICROMITRA SCULPTILIS ENDLICHI Walcott.

Text figure 22.

Micromitra sculptilis endlichi WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 56. (Characterized as below as a new variety.)

This form is represented by a single specimen of a ventral valve. The surface is similar to that of *Micromitra sculptilis* (Meek), but the valve is more elongate, less elevated, and larger (5 mm. in diameter) than the specimens of the latter from the type locality.

The varietal name is given for Mr. F. M. Endlich of the Hayden Survey.

FORMATION AND LOCALITY.—**Upper Cambrian:** (8o) Limestone 2 miles (3.2 km.) north of Aurum, Schell Creek Range, White Pine County, Nevada.

MICROMITRA ZENOBIA n. sp.

Text figure 23.

Most of the specimens of this species are flattened in the shale, but both valves appear to have been moderately and nearly equally convex. The beak of the ventral valve is slightly in advance of the posterior margin and incurves slightly over a well-defined cardinal slope which is nearly straight and almost as wide as the greatest diameter of the shell. The pseudodeltidium is moderately convex and apparently extends about half the distance from the beak to the posterior margin.

Growth lines are fairly coarse and regular. In the ventral valve they bend abruptly at the cardinal slope, on which they are very fine and very irregular. In other words, the cardinal slope is well defined and is covered with an irregular confusion of minute ridges which seem to bear little relation to the concentric ridges on the surface of the shell. This pattern can not be seen on the pseudodeltidium.

In some of the adult shells from the type locality (35k) a faint radial crenulation can be seen near the apex. Fragments of limestone (Locality 57c) contain many small shells, probably the young, with radial folds and a crenulation of the concentric striæ similar to that in *Micromitra sculptilis*. The crenulations have been observed in one perfectly preserved adult specimen. The specimens from the limestone may be distinct.

FORMATION AND LOCALITY.—**Middle Cambrian:** (35k) *Burgess shale member of the Stephen formation, west slope of ridge between Mount Field and Wapta Peak, 1 mile (1.6 km.) northeast of Burgess Pass, above Field; and (58 l) about 1,830 feet (557.8 m.) above the Lower Cambrian in the limestone forming 3b of the Stephen formation [Walcott, 1908c, p. 238 (7)], on the east side of Mount Stephen about 3,000 feet (914.4 m.) above the Canadian Pacific Railway track 3.5 miles (5.6 km.) east of Field; both in British Columbia.*

FIGURE 22.—*Micromitra sculptilis endlichi* Walcott. A, A', Top and side views of the type specimen, a ventral valve from Locality 8o, Upper Cambrian limestones, 2 miles (3.2 km.) north of Aurum, White Pine County, Nevada (U. S. Nat. Mus. Cat. No. 51498).

FIGURE 23.—*Micromitra zenobia* n. sp. Top view of type specimen, a ventral valve from Locality 35k, Middle Cambrian Stephen formation 1 mile (1.6 km.) northeast of Burgess Pass, above Field, British Columbia (U. S. Nat. Mus. Cat. No. 58311).

(57c) About 2,500 feet (762 m.) above the Lower Cambrian and 2,475 feet (754 m.) below the Upper Cambrian in the limestone forming 1 of the Stephen formation [Walcott, 1908f, p. 209]; and (58z) about 1,875 feet (572 m.) above the Lower Cambrian and 3,100 feet (945 m.) below the Upper Cambrian in the limestone forming 2b of the Stephen formation [Walcott, 1908f, p. 211]; both on Mount Bosworth, north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide between British Columbia and Alberta, Canada.

MICROMITRA sp. undt. (Walcott).

Plate III, figure 7.

Iphidea sp. undet., WALCOTT, 1899, Mon. U. S. Geol. Survey, vol. 32, pt. 2, p. 449, Pl. LX, fig. 6. (Described and discussed as below as an undetermined species. The specimen represented by fig. 6 is redrawn in this monograph, Pl. III, fig. 7.)

Iphidella sp. undt., WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 305. (Description and discussion copied from preceding reference.)

Dorsal valve semicircular, slightly convex. Hinge line somewhat shorter than the width of the shell below; nearly straight, the rostral angle about 180°. Beak small, not elevated. Surface ornamented by extremely fine, radiating, and undulating concentric striæ that can be seen in detail only with a strong magnifying glass. Shell substance horny.

This form is associated with *Micromitra sculptilis* (Meek) and, judging from external characters, is closely related to it. The surface ornamentation is of the same character, and, in the absence of the ventral valve, it is difficult to distinguish any specific characters on which to base a new species, although the shell is much larger than that of *M. sculptilis*.

FORMATION AND LOCALITY.—Middle Cambrian: (302b) Limestones near Crowfoot Ridge, Gallatin quadrangle (U. S. Geol. Survey), Yellowstone National Park, Wyoming.

PATERINA Beecher,^a subgenus of MICROMITRA.

- Iphidea* Billings, WALCOTT (in part), 1897, Proc. U. S. Nat. Mus., vol. 19, pp. 707-711. (Discussed. The genus as discussed includes species now referred to *Micromitra*, *Micromitra (Paterina)*, and *Micromitra (Iphidella)*.)
- Paterina* Beecher, WALCOTT, 1897, idem, p. 708. (Discussed as synonym of *Iphidea*.)
- Iphidea* Billings, SCHUCHERT (in part), 1897, Bull. U. S. Geol. Survey No. 87, p. 233. (Merely refers *Micromitra* and *Paterina* to *Iphidea*.)
- Iphidella* WALCOTT (in part), 1905, Proc. U. S. Nat. Mus., vol. 28, p. 304. (Merely proposed to replace *Iphidea*, but includes reference to specimens belonging with *Micromitra*, *Micromitra (Paterina)*, and *Micromitra (Iphidella)*.)
- Iphidea* Billings, GRABAU and SHIMER (in part), 1907, North American Index Fossils, vol. 1, p. 201. (Described, and includes species referred to each of the subgenera *Paterina* and *Iphidella*.)
- Micromitra (Paterina)* (Beecher), WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of subgenus.)

All of the species of *Micromitra* with plain concentric striae on the outer surface are grouped under *Paterina* as a subgenus. Beecher [1891, p. 345] quoted "*Obolus labradoricus* Billings" as the type of his genus *Paterina*, supposing that the species represented the simplest form of brachiopod known. The genus was subsequently shown [Walcott, 1897b, p. 707] to have been previously described [Meek, 1873, p. 479] under a different name, *Micromitra (Iphidea)* being preoccupied [Schuchert, 1905, p. 329]), but as it appears necessary to group the shells of which *Micromitra (Paterina) labradorica* (Billings) is a typical example under a subgenus, I have adopted *Paterina* as the name for it.

Type.—*Kutorgina labradorica swantonensis* Walcott [1890, p. 36].

Beecher studied the specimens of the variety *Micromitra (Paterina) labradorica swantonensis* (Walcott) which were in my laboratory in the United States National Museum and did not at the time have the specimens of "*Obolus labradoricus*" from the St. Lawrence Valley. He mistook the duplicate specimens of the variety for the species, and it was from the material he examined that the area of the ventral valve was subsequently worked out, as shown on Plate II, figures 3d, 3e, and 3f.

A list of the species referred to *Paterina* has been given under the genus *Micromitra* (p. 336).

- Iphidea bella* Billings, OEHLERT, 1887, Manuel de conchyliologie, by Fischer, p. 1270, fig. 1026. (Mentioned in French. Fig. 1026 is copied from Billings, 1872b, fig. 13, p. 477.)
- Iphidea bella* Billings, WALCOTT, 1891, Tenth Ann. Rept. U. S. Geol. Survey, p. 608, Pl. LXVII, fig. 6. (Mentioned. Fig. 6 is copied from Billings, 1872b, fig. 13, p. 477.)
- Not *Iphidea bella* HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York, for 1891, p. 249, Pl. IV, figs. 4 and 5. (Mentioned. Referred in this monograph to *Micromitra (Paterina) labradorica swantonensis*.)
- Iphidea bella* Billings, HALL and CLARKE (in part), 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 98, fig. 54, not Pl. IV, figs. 8 and 9. (Mentioned in the text. Fig. 54 is copied from Billings, 1872b, fig. 13, p. 477. The specimens represented by figs. 8 and 9 are referred in this monograph to *Micromitra (Paterina) labradorica swantonensis*.)
- Iphidea bella* Billings?, GRABAU, 1900, Occas. Papers Boston Soc. Nat. Hist., No. 4, vol. 1, pt. 3, pp. 617-618, Pl. XXXI, fig. 2. (Described and discussed.)
- Micromitra bella* (Billings), CLARK and MATHEWS, 1906, Maryland Geol. Survey, vol. 6, pt. 1, p. 252, Pl. XVI, fig. 15. (No text reference. Fig. 15 is copied from Walcott, 1886, Pl. VII, fig. 4.)
- Iphidea bella* Billings, GRABAU and SHIMER, 1907, North American Index Fossils, vol. 1, p. 201, fig. 234h, p. 199. (Described. Fig. 234h is copied from Billings, 1872b, fig. 13, p. 477.)

The shell described and illustrated by Billings [1872b, pp. 477-478] had a large false area and a convex pseudodeltidium, the width of which at the hinge line was stated to be nearly one-third the whole width of the shell.

I received from Whiteaves what was supposed to be the type specimen of the ventral valve, from Trois Pistoles, but I find that it does not belong to the species described by Billings [1872b, p. 477]. The area is strongly marked, but the pseudodeltidium in the specimen before me is very short, not over one-fifth the height of the deltidial area. In this respect it resembles the pseudodeltidium of *Micromitra (Paterina) crenistria* (Walcott). It is described in this monograph as *M. (P.) logani* (Walcott). Under date of July 23, 1896, Professor Whiteaves wrote that there were no other specimens or electrotypes of the types of *M. (P.) bella* (Billings) in the collections of the Geological Survey of Canada, nor of the closely allied species of the same genus from Topsail Head, mentioned by Billings [1872b, p. 478]. (See pp. 335 and 350, and Pl. II, figs. 1 and 1c.)

Billings [1872b, pp. 477-478] describes the genus and species as follows:

The ventral? valve of *I. bella* is conical, strongly elevated at the beak, hinge line nearly straight, posterior angles narrowly rounded, sides and front nearly uniformly rounded, forming rather more than a semicircle. Posterior side with a large false area and a convex pseudodeltidium, the width of which at the hinge line is nearly one-third the whole width of the shell. The dorsal valve is semicircular, moderately convex, most elevated at the beak. The hinge line appears to be straight. The form and structure of the posterior side (such as the area, foramen, deltidium, etc.) can not be made out from the specimen, owing to its imperfection. The surface is covered with fine concentric striæ, which in the ventral? valve are continued around on the area. Of these striæ there appear to be from fifteen to twenty in the width of one line, their size varying somewhat in different parts of the specimen. There are also a few obscure radiating striæ. Width of ventral valve, seven lines; length, five lines; height, two lines.

Very little is to be added to this description from a study of the material from the north side of the Straits of Belleisle and from Pennsylvania, except that the examination of a number of specimens has revealed the fact that there is no true perforation in the beak. Billings states that in the specimen described by him there is an aperture in the beak, but in another there is no appearance of one. I observed a narrow furrow near the apex of the beak in a specimen from L'Anse au Loup, Labrador, but there was no aperture through the shell. Several other specimens afford no traces of even a slight slit in front of the beak. The presence of this depression or furrow is mentioned, and its character set forth in the description of the genus *Micromitra* (p. 335).

FORMATION AND LOCALITY.—Lower Cambrian: (2n) Limestone boulders in conglomerate, along the shore of the St. Lawrence, near Trois Pistoles, Temiscouata County; and (2o) limestone boulders in conglomerate on shore at east entrance to harbor at Bic, Rimouski County; both in Quebec, Canada.

(314e [Billings, 1872b, p. 478]) Limestone at Topsail Head, Conception Bay, Newfoundland.

(392a) Limestone [Walcott, 1891b, p. 234] at L'Anse au Loup, on the north shore of the Straits of Belleisle, Labrador.

(326g [Grabau, 1900, p. 617]) Limestones at East Point, Nahant, Essex County, Massachusetts.

(49) Sandstone on Codorus Creek, 0.125 mile (0.2 km.) below Meyer's mill, near Emigsville, York County;

(346a) limestones in Landis Valley, Lancaster County; and (49w) limestones in railroad cut 0.25 mile (0.4 km.) south of Emigsville, York County; all in Pennsylvania.

(25) Sandstone just above Parker's quarry, near Georgia, Franklin County, Vermont.

MICROMITRA (PATERINA) CRENISTRIA (Walcott).

Plate III, figures 4, 4a-b.

Iphidea crenistria WALCOTT, 1897, Proc. U. S. Nat. Mus., vol. 19, p. 713, Pl. LIX, figs. 4, 4a-b. (Described and discussed essentially as below as a new species. The specimen represented by figs. 4, 4a-b is redrawn in this monograph, Pl. III, figs. 4, 4a-b.)

Ventral valve subconical, beak nearly apical, curving slightly over to the pseudodeltidium. False area very narrow, separated from the curvature of the shell by being turned somewhat abruptly backward. Pseudodeltidium comparatively broad, but decidedly short as compared with that of *Micromitra (Paterina) bella* (Billings) or *M. (P.) superba* (Walcott). It is more the type of that of *M. (P.) labradorica* (Billings). It is strongly arched, leaving a broad, high space between it and the plane of the shell.

Dorsal valve unknown. Surface of ventral valve marked by very fine, slightly crenulated striæ that are so crowded on the false area that they are nearly lost, and only one or two varices of growth and a few striæ are shown on the pseudodeltidium. No traces of an apical opening have been seen. On some shells a faint furrow is seen on the apex.

This species is clearly distinguished from other described forms of the subgenus by its highly arched pseudodeltidium and crenulated surface striæ.

An imperfect ventral valve from the upper portion of the Secret Canyon shale of the Eureka district section, Nevada, has somewhat coarser striæ than this species, but otherwise it appears to be the same. Specimens from near Schellbourne, Nevada, appear to be identical with the Grand Canyon form. A single imperfect ventral valve, from the Orr formation, 930 feet above the base of the Upper Cambrian, in the House Range section of Utah, is very much like the specimen from the Secret Canyon shale of Nevada and is tentatively placed with it under this species. The Grand Canyon, Utah, and Nevada shells appear to be descendants of *M. (P.) labradorica* of the Lower Cambrian and its varieties in the lower portion of the Middle Cambrian of the Cordilleran region.

This form owes its specific name to the finely crenulated striæ with which its outer surface is characterized.

FORMATION AND LOCALITY.—**Upper Cambrian:** (313) Limestone 0.75 mile (1.2 km.) east-northeast of McGill post office, White Pine County, Nevada.

Middle Cambrian: (75) "Tonto" sandstone, near the water's edge, at the mouth of Kanab Canyon, where it enters the Grand Canyon of the Colorado; (73b) sandstone in upper part of Tonto group, lower portion of Kwagunt Valley, Grand Canyon of the Colorado; and (74) sandstone about 300 feet (91.4 m.) above the base of the Tonto group, at the head of Nunkoueap Valley, Grand Canyon of the Colorado; all in Arizona.

(313b) Limestone 3 miles (4.8 km.) north-northeast of Schellbourne, Schell Creek Range, White Pine County, Nevada.

(13b) Sandstones of the Rome formation, northeast of Rhea Springs [Hayes, 1894, areal geology sheet], Roane County, Tennessee.

Specimens somewhat doubtfully referred to this species occur at the following localities:

Upper Cambrian: (30j) About 950 feet (289.6 m.) above the Middle Cambrian and 2,450 feet (746.8 m.) below the top of the Upper Cambrian near the base of the arenaceous shales and limestone forming 1e of the Orr formation [Walcott, 1908f, p. 176], on Orr Ridge, about 5 miles (8 km.) south of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.

Middle Cambrian: (58) Shaly limestones in the upper beds of the Secret Canyon shale, east side of New York and Secret canyons, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

MICROMITRA (PATERINA) ETHERIDGEI (Tate).

Plate III, figures 10, 10a-c.

Platyceras etheridgei TATE, 1892, Trans. Roy. Soc. South Australia for 1892, vol. 15, pt. 2, p. 184, Pl. II, figs. 7a-c. (Described and discussed as a new species. The two specimens represented by figs. 7a-c are redrawn in this monograph, Pl. III, figs. 10, 10a-b.)

The original description by Tate follows:

Shell small, broadly conical; apex obtuse, posterior, recurved, but not spiral, usually protruding beyond the posterior margin; aperture roundly oval, but irregular in outline, subtruncated and narrowed posteriorly. Surface ornamented with rather thick subimbricating concentric folds of growth, and curved beneath the apex coincidentally with the posterior margin; faintly radially wrinkled.

This very common species exhibits considerable variability in the outline of the aperture, and the amount of backward projection of the apex. The shells seem to have lived on irregular surfaces, and in some instances at least upon trilobites. The proportionate measures of the basal diameter and height are as 4 to 3; the longest diameter observed is 6 mills.

The examination of the type specimen of this species shows that the shell substance is corneous, that there is a true false area, and that the species is closely related to *Micromitra (Paterina) superba* (Walcott). All of the specimens in the collection are ventral valves, and these differ considerably in elevation, apparently owing to the upward arching of the posterior margin beneath the false area. This characteristic distinguishes the species from *M. (P.) superba* and allied forms.

The specific name was given in honor of Dr. R. Etheridge, jr.

FORMATION AND LOCALITY.—**Middle ? Cambrian:** (315 [Tate, 1892, p. 184]) Limestone at Curramulka, Yorke Peninsula, South Australia.

MICROMITRA (PATERINA) LABRADORICA (Billings).

Plate II, figures 2, 2a-f.

- Obolus labradoricus* BILLINGS, 1861, Geol. Survey Canada, Paleozoic Fossils, vol. 1, p. 6, fig. 6. (Described as a new species. The specimen represented by fig. 6 is redrawn in this monograph, Pl. II, fig. 2.)
- Obolus labradoricus* BILLINGS, 1861, Report on the Geology of Vermont, vol. 2, p. 946, fig. 345. (Copy of preceding reference.)
- Obolus labradoricus* BILLINGS, 1862, Report on the Economic Geology of Vermont, by Hager, p. 218, fig. 345. (Copy of preceding reference.)
- Obolus labradoricus* BILLINGS, 1863, Geol. Survey Canada, Fifteenth Rept. Progress, p. 284, fig. 291. (No text reference. Fig. 291 is copied from Billings, 1861b, fig. 6, p. 6.)
- Iphidea labradorica* BILLINGS, 1872, Canadian Naturalist, 2d ser., vol. 6, No. 4, p. 478. (Merely changes generic reference.)
- Iphidea labradorica* BILLINGS, 1874, Geol. Survey Canada, Paleozoic Fossils, vol. 2, pt. 1, p. 76. (Copy of preceding reference.)
- Kutorgina labradorica* (Billings), WALCOTT (in part), 1886, Bull. U. S. Geol. Survey No. 30, p. 104, not Pl. IX, figs. 2, 2a-b. (Original description, Billings, 1861b, p. 6, copied and species discussed. The specimens figured, however, belong with *Micromitra (Paterina) labradorica swantonensis*.)
- Not *Paterina labradorica* BEECHER, 1891, Am. Jour. Sci., 3d ser., vol. 41, footnote, pp. 345-346, Pl. XVII, figs. 1 and 2. (The specimens here referred to belong with *Micromitra (Paterina) labradorica swantonensis*.)
- Kutorgina labradorica* (Billings), WALCOTT, 1891, Tenth Ann. Rept. U. S. Geol. Survey, p. 609, Pl. LXIX, figs. 3, 3a-b. (Mentions new locality. The specimens represented by figs. 3, 3a-b are redrawn in this monograph, Pl. II, figs. 2d, 2c, and 2a, respectively.)
- Not *Paterina labradorica* HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York, for 1891, p. 247, fig. 258. (Genus *Paterina* described. Fig. 258 is copied from Walcott, 1886b, Pl. IX, figs. 2b and 2a, but the specimens belong with *Micromitra (Paterina) labradorica swantonensis*.)
- Iphidea labradorica* (Billings), SCHUCHERT (in part), 1897, Bull. U. S. Geol. Survey No. 87, p. 234. (Accepts Billings's reference of "*Obolus labradoricus*" to *Iphidea*, but includes reference to specimens of *Micromitra (Paterina) labradorica swantonensis*.)
- Iphidella labradorica* WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 307. (Merely changes generic reference.)

Ventral valve depressed, conical; the beak high and arched over the narrow area. Cardinal slopes flattened so as to form a narrow false area, which is clearly defined from the curvature of the shell by a sharp angle; pseudodeltidium unknown.

Dorsal valve moderately convex, transverse, the hinge line being usually a little shorter than the greatest width of the shell below. Beak small, slightly incurving over the pseudodeltidium. In some specimens there is a broad low mesial sinus, while in others this feature is scarcely discernible. Cardinal slope nearly vertical, forming a clearly defined narrow area, broken at the center by a broad pseudodeltidium, the center of which is marked by a rather broad, slight groove. The pseudodeltidium is well shown in two specimens, but the details of its characters are not so well exhibited as in specimens of the dorsal valve of *Micromitra (Iphidella) pannula* (White). Striæ of growth cross the false area and pseudodeltidium.

The surface is marked by rather fine concentric striæ that are quite regular near the apex of the shell, but less so outward toward the margin, as shown by the type specimens that Whiteaves kindly sent on to me for study. These also show fine, radiating striæ that cross the concentric striæ and lines of growth, giving to the striæ a slightly crenulated appearance somewhat similar to that of *Micromitra (Paterina) prospectensis* (Walcott). Where the shell is exfoliated, radiating striæ are distinctly shown on the cast of the interior. On specimens from the limestone carrying *Olenellus*, etc., at Topsail Head, Conception Bay, Newfoundland, the surface striæ are less distinctly marked and the shells are smaller, but there appears to be no specific difference between those from the Straits of Belleisle. Shell substance corneous.

With a type specimen from L'Anse au Loup before me for comparison with the form from the Lower Cambrian limestone east of Swanton, Vermont, I am still inclined to distinguish the latter as the variety *swantonensis*. The striæ of the Swanton shells are usually finer and more regular and the valves less transverse in proportion to the length. It is quite probable that these differences would largely disappear on the comparison of a larger series of specimens from the type locality, as there is a considerable range of variation among those from east of Swanton and those from Topsail Head.

In the Hanford Brook section of New Brunswick I found very good illustrations of this species in Matthew's "Etcheminian."

This form owes its specific name to its occurrence at the Straits of Belleisle, Labrador.

FORMATION AND LOCALITY.—**Lower Cambrian:** (41a) Limestone [Walcott, 1891b, p. 260] on the mainland beneath Topsail Head, Conception Bay; (314e [Walcott, 1886a, p. 150] limestone at Topsail Head, Conception Bay; (5r) limestone near the railroad track 1.5 miles (2.4 km.) west of the railway station at Manuels, Conception Bay; (5t) shale and limestone nodules about 20 feet (6 m.) above the base of the Cambrian, on Redrock Point, near Chapple Cove, Hollywood Point, Conception Bay; (51) limestone on Smith Point, in Smith Sound, Trinity Bay; and (314f) limestone of B7 of the section at Bonne Bay [Walcott, 1891b, p. 255]; all in Newfoundland.

(392a) *Limestones* [Walcott, 1891b, p. 254] at *L'Anse au Loup* on the north shore of the Straits of Belleisle, Labrador.

(3a) 450 feet (137.1 m.) below the quartzite in the St. John formation and over 500 feet (152.4 m.) below the *Protolenus* zone of Matthew [Walcott, 1900, pp. 320-322], Hanford Brook; and (301v [Walcott, 1900, p. 322]) sandy shales of Division 2b of the "basal series" of Matthew, on Hanford Brook; both in St. John County, New Brunswick.

(2o) Limestone boulders in conglomerate on shore at east entrance to harbor at Bic, Rimouski County, Quebec.

(2b) Limestone just north of Beman Park, in the northeastern part of the city of Troy, Troy quadrangle (U. S. Geol. Survey), Rensselaer County, New York.

(304o) Sandstone at Nuneaton, England.

(1v) Shales of No. 3 of the Silver Peak group, Barrel Spring section [Walcott, 1908f, p. 189], 3 miles (4.8 km.) north of Valcald Spring and 4 miles (6.4 km.) west-northwest of the Drinkwater mine, Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County, Nevada.

(57r and 58s) About 150 feet (46 m.) below the Middle Cambrian near the base of the limestones forming 3 of the Mount Whyte formation [Walcott, 1908c, p. 241 (10)], just above the tunnel on the north shoulder of Mount Stephen, about 3 miles (4.8 km.) east of Field, British Columbia.

Specimens somewhat doubtfully referred to this species occur at the following locality:

Lower Cambrian: (2r) Limestone boulders in a conglomerate in a cut on the Intercolonial Railway, 2 miles (3.2 km.) west of Bic railway station, Rimouski County, Quebec.

MICROMITRA (PATERINA) LABRADORICA ORIENTALIS (Walcott).

Plate II, figure 11.

Iphidella labradorica orientalis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 305-306. (Characterized as below as a new variety.)

Only one dorsal valve of this shell occurs in the collection. Its general form and surface characters are very much like those of *Micromitra (Paterina) labradorica swantonensis* (Walcott) [Pl. II, figs. 3, 3a-f]. The varietal name is given more on account of the fact that this shell occurs in China and the variety *swantonensis* on the eastern side of the North American continent than from any marked differences between the shells from the two localities. It may be that with a good series of shells from China differences would be found that are not to be determined with only the single shell for comparison.

FORMATION AND LOCALITY.—**Middle Cambrian:** (C9) Lower limestone member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 39 (3d list of fossils)], 3 miles (4.8 km.) southwest of Yenchuang, Sintai district, Shantung, China.

MICROMITRA (PATERINA) LABRADORICA SWANTONENSIS (Walcott).

Plate II, figures 3, 3a-f.

Kutorgina labradorica WALCOTT (in part) [not (BILLINGS)], 1886, Bull. U. S. Geol. Survey No. 30, Pl. IX, figs. 2, 2a-b. (The text reference [on page 104] includes only specimens belonging to the species *Micromitra (Paterina) labradorica*. The figures represent specimens of the variety *swantonensis*, which are redrawn in this monograph, Pl. II, figs. 3, 3a-b, respectively.)

Kutorgina labradorica swantonensis WALCOTT, 1890, Proc. U. S. Nat. Mus. for 1889, vol. 12, p. 36. (Characterized as a new variety.)

Paterina labradorica BEECHER [not (BILLINGS)], 1891, Am. Jour. Sci., 3d ser., vol. 41, footnote, pp. 345-346, Pl. XVII, figs. 1 and 2. (Discussed as the type of the new genus *Paterina*. Figs. 1 and 2 are copied from Walcott's figures, 1886b, Pl. IX, figs. 2b and 2, respectively.)

Kutorgina labradorica swantonensis WALCOTT, 1891, Tenth Ann. Rept. U. S. Geol. Survey, p. 609, Pl. LXIX, figs. 2, 2a-b. (Characterized. Figs. 2, 2a-b are copied from Walcott, 1886b, Pl. IX, figs. 2, 2a-b.)

Paterina labradorica HALL and CLARKE [not (BILLINGS)], 1892, Eleventh Ann. Rept. State Geologist New York for 1891, p. 247, fig. 258. (Genus *Paterina* described. Fig. 258 is copied from Walcott, 1886b, Pl. IX, figs. 2b and 2a.)

Iphidella bella HALL and CLARKE [not BILLINGS], 1892, idem, p. 249, Pl. IV, figs. 4 and 5. (Mentioned.)

- Iphidea bella* HALL and CLARKE (in part) [not BILLINGS], 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 98, Pl. IV, figs. 8 and 9 (not fig. 54, p. 98, which is referred in this monograph to *Micromitra (Paterina) bella*). (Mentioned in the text. Figs. 8 and 9 are copied from Hall and Clarke, 1892a, Pl. IV, figs. 4 and 5, respectively.)
- Iphidea labradorica* SCHUCHERT (in part) [not (BILLINGS)], 1897, Bull. U. S. Geol. Survey No. 87, p. 234. (Accepts Billings's reference of "*Obolus labradoricus*" to *Iphidea*, but includes reference to specimens of both *Micromitra (Paterina) labradorica* and its variety *swantonensis*.)
- Iphidea labradorica swantonensis* (Walcott), SCHUCHERT, 1897, idem, p. 234. (Merely changes generic reference.)
- Iphidella labradorica swantonensis* WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 307. (Merely changes generic reference.)
- Iphidea swantonensis* (Walcott), GRABAU and SHIMER, 1907, North American Index Fossils, vol. 1, p. 201, figs. 234i and 234j, p. 199. (Described. Figs. 234i and 234j are copied from Walcott, 1886b, Pl. IX, figs. 2a and 2b, respectively.)

The general form of the two valves of this variety is so close to that of *Micromitra (Paterina) labradorica* (Billings) (p. 347) that it will not be necessary to repeat the description. The differences existing in the variety *swantonensis* have been mentioned in describing the species. The variety is exceedingly abundant in the *Olenellus*-bearing limestone, 2 miles (3.2 km.) east of Swanton, Vermont, in association with *Kutorgina cingulata* (Billings). Shell substance corneous.

The most interesting addition to our knowledge of the species is the discovery of the presence of a narrow area on the ventral valve and a short pseudodeltidium, as shown in a longitudinal section (Pl. II, figs. 3c-f). The existence of the area and pseudodeltidium in the ventral valve of the variety *swantonensis*, the form studied by Beecher, and in the dorsal valve of *M. (P.) labradorica*, was unknown at the time that Beecher [1891, p. 345] selected *M. (P.) labradorica swantonensis* (see p. 344) as the simplest form or prototype (*Paterina*), "preserving throughout its development the main features of a protegulum, and showing no separate or distinct stages of growth."

The discovery of the area and pseudodeltidium refers the species and its varieties to the genus *Micromitra* [Walcott, 1897b, p. 707].

The exact stratigraphic position of Locality 87 has not been made out, but from the associated species of *Agnostus* and *Ptychoparia*, it is evidently to be referred to the Middle Cambrian.

This form owes its varietal name to its occurrence in the vicinity of Swanton, Vermont.

FORMATION AND LOCALITY.—**Middle Cambrian:** (87) Conglomeratic limestone 1 mile (1.6 km.) south-southwest of Highgate Falls, Franklin County, Vermont.

Lower Cambrian: (25a) Limestone on the Hall (Donaldson's) farm, 2 miles (3.2 km.) east of Swanton; (319z) sandy limestone 2.5 miles (4 km.) east of Swanton; (26) sandstone northeast of the Corman farm buildings, east of Highgate Springs; and (319y) sandstone 2 miles (3.2 km.) east-southeast of Highgate Springs; all in Franklin County, Vermont.

(319x) Limestone at the crossing of East Creek and Grove Street, 1.25 miles (2 km.) north of Rutland, Rutland County, Vermont.

MICROMITRA (PATERINA) LABRADORICA UTAHENSIS (Walcott).

Text figure 24, page 350; Plate II, figures 8, 8a.

Iphidella labradorica utahensis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 306. (Characterized as a new variety.)

The general form of this variety is much like that of *Micromitra (Paterina) labradorica* (Billings). It differs from it in the fine, threadlike, concentric striae of the outer surface, in this respect approaching *M. alabamaensis* (Walcott) and *M. (P.) superba* (Walcott). During the field season of 1906 fine specimens of this variety were found in the limestones 760 and 1,200 feet above the quartzitic sandstones referred to the Lower Cambrian. A ventral valve 6 mm. in width has a convex pseudodeltidium 1.25 mm. in length, with a width of 2.5 mm. at its slightly arched margins. The variety *swantonensis* also has a wide, convex pseudodeltidium (Pl. II, figs. 3e, 3f).

FORMATION AND LOCALITY.—**Middle Cambrian:** (30c) About 1,050 feet (320 m.) above the Lower Cambrian and 3,350 feet (1,021.1 m.) below the Upper Cambrian in the shales forming 1d of the Swasey formation [Walcott, 1908f, p. 182], at the head of Dome Canyon, House Range [Walcott, 1908f, Pl. XIII], Millard County; (3d) concretionary limestone about 100 feet (30.5 m.) above the quartzitic sandstones of the Cambrian, at Ophir, Oquirrh Range, Tooele County; (30p) about 125 feet (38 m.) above the Cambrian quartzitic sandstones, on the north side of Ogden Canyon,

about 1 mile (1.6 km.) above its mouth, east of Ogden, Weber County; (30u) about 250 feet (76.2 m.) above the top of the Cambrian quartzitic sandstones, in sandy shales, 4 miles (6.4 km.) northwest of Promontory Point (on the "Lucin cut-off" of the Union Pacific Railway), about halfway up west end of ridge, north of Great Salt Lake, Boxelder County; (34m) limestone about 765 feet (233.2 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County; and (32d) shales about 150 feet (45.7 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], on the east side of the south fork of Paradise Dry Canyon (locally known as East Fork), east of Paradise, Cache Valley, Cache County; all in Utah.

FIGURE 24.—*Micromitra (Paterina) labradorica utahensis* (Walcott). A, A', A'', Top, side, and back views of a ventral valve from Locality 54m, Middle Cambrian limestones in Blacksmith Fork Canyon, Cache County, Utah (U. S. Nat. Mus. Cat. No. 51434).

p. 196]; and (54m) about 1,225 feet (373.4 m.) above the Brigham quartzite and 2,950 feet (899.2 m.) below the Upper Cambrian in the upper part of the limestone forming 1a of the Ute limestone [Walcott, 1908f, p. 195]; all in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

MICROMITRA (PATERINA) LABRADORICA var. undt.

This form is distinguished from *Micromitra (Paterina) labradorica* (Billings) and its varieties by having much finer and more closely arranged concentric striæ. In other characters it approaches very closely to the typical forms of the species.

FORMATION AND LOCALITY.—Lower Cambrian: (1v) Shales of No. 3 of the Silver Peak group, Barrel Spring section [Walcott, 1908f, p. 189], 3 miles (4.8 km.) north of Valcalda Spring and 4 miles (6.4 km.) west-northwest of the Drinkwater mine, Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County, Nevada.

MICROMITRA (PATERINA) LOGANI (Walcott).

Plate II, figures 6, 6a-b.

Iphidea logani WALCOTT, 1897, Proc. U. S. Nat. Mus., vol. 19, pp. 711-712, Pl. LIX, figs. 2, 2a-b. (Described and discussed essentially as below as a new species. The specimen represented by figs. 2, 2a-b is redrawn in this monograph, Pl. II, figs. 6, 6a-b.)

Ventral valve conical, transverse in outline at the base, almost semicircular. Beak minute, incurving over the pseudodeltidium. Cardinal slopes rounded and flattened so as to form a fairly well-defined false area that is broken by a very wide triangular space. Pseudodeltidium arching upward, forming a narrow, sloping shelf beneath the beak, the angle of slope from the summit of the shell over the beak and pseudodeltidium being nearly the same as the slope from the summit to the front.

Surface marked by very fine concentric striæ and somewhat coarser lines of growth. Under a high power slight traces of radiating striæ may be observed. The concentric striæ pass around over the false area and cross the pseudodeltidium. Shell substance corneous.

Observations.—This specimen was received from Whiteaves, of the Geological Survey of Canada, as the type of *M. (P.) bella* (Billings). It differed, however, so materially from the description of that species [Billings, 1872b, pp. 477-478] and the figure illustrating it that I found it necessary to give it a distinct specific designation. (See pp. 335 and 345.)

This species approaches most nearly *M. (P.) crenistria* (Walcott) in its short pseudodeltidium and finely striated surface. It differs, however, in the character of the surface striæ, the form of the false area, and the pseudodeltidium.

The specimen bears the label "Trois Pistoles, 1868, T. C. Weston." It was collected from a boulder in the conglomerate at that locality, and it is probably of Middle Cambrian age, though this can not be stated positively, as there are no associated fossils. Billings [1872b, p. 478] speaks of the occurrence of fragments of trilobites in the boulder containing his type of *Micromitra (Paterina) bella*. He does not mention the genera or species.

The conglomerates of this formation, according to Logan, form 9 separate layers, from 2 to 16 feet thick, bedded in gray calcareous sandstone. The geologic age of the deposit of the matrix is supposed to be Upper Cambrian or Lower Ordovician. The age of the boulders can only be determined by the fossils found in each.

The specific name was given in honor of Sir William E. Logan.

FORMATION AND LOCALITY.—**Middle? Cambrian:** (2n) Limestone in conglomerate on shore near Trois Pistoles, on St. Lawrence River, Province of Quebec, Canada.

MICROMITRA (PATERINA) MAJOR (Walcott).

Text figure 25.

Iphidella major WALCOTT (in part), 1905, Proc. U. S. Nat. Mus., vol. 28, p. 304. (Described and discussed somewhat as below as a new species. Specimens now referred to *Micromitra (Paterina) williardi* were included with the specimens representing *Micromitra (Paterina) major* when this description was given.)

Obolus smithi WALCOTT (in part), 1908, Smithsonian Misc. Coll., vol. 53, No. 3, Pl. VII, fig. 9 (not fig. 9a, which represents a specimen of *Obolus smithi*). (No text reference. Fig. 9, which is reproduced in this monograph as fig. 25, was inserted on Pl. VII of the above reference by mistake. All of the figures representing the two species (*Obolus smithi* and *Micromitra (Paterina) major*) happened to be grouped on the same preliminary plate, and when two figures were chosen to represent *Obolus smithi* in the paper referred to, one of the figures representing *Micromitra (Paterina) major* was accidentally included.)

Ventral valve subconical, with the apex slightly in front of the posterior margin. A minute beak appears to incurve over the pseudodeltidium. Cardinal slope rather abruptly rounded, so as to indicate a rather narrow false area. Pseudodeltidium broad and convex, with its lower margin arched so as to leave a space between it and the plane of the margin of the shell. Dorsal valve slightly convex, with a narrow area.

Surface, so far as can be determined from the badly preserved material, marked by rather strong growth lines and very fine concentric striae. The largest dorsal valve has a length of 10.5 mm.; width, 13 mm. Only one small ventral valve is known.

Observations.—The material representing this species is more or less compressed and distorted in the argillaceous shales in which it occurs. In general form it is not unlike that of *Micromitra (Paterina) labradorica* (Billings) (Pl. II, figs. 2, 2a-f), but it differs in its nearly smooth surface and the position of the apex. It is, however, the southern Appalachian representative of that species. The original description of this species was based on specimens now referred to this species and to *Micromitra (Paterina) williardi* Walcott. Very good specimens of the latter are now available from two localities near Helena, Alabama.

This form owes its specific name to its large size.

FORMATION AND LOCALITY.—**Lower Cambrian:** (56c) Rome ("Montevallo") formation along road just north of Buck Creek, 1.125 miles (1.8 km.) northeast of Helena; and (17b) Rome ("Montevallo") formation 4 miles (6.4 km.) south of Helena; both in Shelby County, Alabama.

A dorsal valve similar to the one illustrated above occurs at the following locality:

Middle Cambrian: (90) Conasauga ("Coosa") shale on Edward's farm, near Craigs Mountain, about 10 miles (16.1 km.) southeast of Center, Cherokee County, Alabama.

MICROMITRA (PATERINA) PHILLIPSI (Holl).

Plate III, figure 8.

Obolella phillipsi HOLL, 1865, Quart. Jour. Geol. Soc. London, vol. 21, pt. 1, p. 102, figs. 10a-c. (Described as a new species. The specimen represented by figs. 10b and 10c is redrawn by Davidson, 1866, Pl. IV, figs. 17a and 17c, and Davidson's figures are copied in this monograph, Pl. III, fig. 8.)

Obolella? phillipsi Holl, DAVIDSON, 1866, British Fossil Brachiopoda, vol. 3, pt. 7, No. 1, pp. 62-63, Pl. IV, figs. 17-19. (Described and discussed. Figs. 17a and 17c are drawn from the specimen represented in figs. 10b and 10c of the preceding reference, and are reproduced in this monograph, Pl. III, fig. 8.)

Kutorgina cingulata DAVIDSON [not (BILLINGS)], 1868, Geol. Mag., vol. 5, p. 312, Pl. XVI, fig. 10. (Discussed.)

FIGURE 25.—*Micromitra (Paterina) major* (Walcott). Exfoliated dorsal valve from Locality 56c, Lower Cambrian beds in Rome formation ("Montevallo shale"), 1.125 miles (1.8 km.) northeast of Helena, Shelby County, Alabama (U. S. Nat. Mus. Cat. No. 51499).

This figure was published [Walcott, 1908d, Pl. VII, fig. 9] as representing the dorsal valve of *Obolus smithi* and was given Cat. No. 51611a. As explained in the note under the second reference in the synonymy, this was a mistake.

- Kutorgina cingulata* DAVIDSON [not (BILLINGS)], 1871, British Fossil Brachiopoda, vol. 3, pt. 7, No. 4, pp. 342-343, Pl. I, fig. 25. (Discussed. Fig. 25 is copied from fig. 10 of preceding reference (p. 351) and erroneously referred to in the description of Pl. I as "*Kortugina cingulata*.")
- Obolella phillipsi* HOLL, PHILLIPS, 1871, Geology of Oxford and the Valley of the Thames, p. 68, Diagram XVII, fig. 12. (No text reference.)
- Obolellus? phillipsi* (HOLL), ROEMER, 1876, Lethæa geognostica, pt. 1, Lethæa palæozoica, atlas, Pl. II, figs. 6a-d. (No text reference. Figs. 6a-d are copied from Davidson, 1866, Pl. IV, figs. 19, 17a, 17c, and 17b, respectively.)
- Obolella phillipsia* HOLL, DALL, 1877, Bull. U. S. Nat. Mus. No. 8, p. 41. (Mentioned as possibly belonging to an undescribed genus.)
- Kutorgina cingulata* DAVIDSON [not (BILLINGS)], 1883, British Fossil Brachiopoda, vol. 5, pt. 2, p. 212. (Characterized.)
- Kutorgina cingulata* WALCOTT (in part) [not (BILLINGS)], 1886, Bull. U. S. Geol. Survey No. 30, pp. 102-104. (Specimens now referred to *Micromitra (Paterina) phillipsi* were included with the specimens representing *Kutorgina cingulata* when this description was written.)
- Kutorgina cingulata phillipsi* (HOLL), MATLEY, 1902, Quart. Jour. Geol. Soc. London, vol. 58, pt. 1, pp. 145-147. (Described and discussed as a variety.)

The original description by Holl follows:

Semicircular, slightly broader than long; hinge-line straight, nearly equal to the greatest width of the shell. Ventral valve prominent at the beak, depressed near the margin; beak small, round, pointed, and situated close to the posterior margin. Dorsal valve evenly convex, slightly depressed at the angles; umbo obtuse. A slight mesial depression toward the anterior border in both valves. Surface marked with numerous moderately fine, sharply defined, rather unequal, concentric striæ, at about their own width apart. Length of a large specimen one-fourth inch, width one-third inch.

The shell structure, where the outer layer has become exfoliated, is strongly punctate.

Observations.—Davidson [1868, p. 312] refers this form to *Kutorgina cingulata* (Billings) under the belief that the American and English species occur at the same relative geologic horizon. The American species, however, occurs in association with the *Olenellus* fauna. With the identification of the types of *Kutorgina cingulata* (Billings) and *Kutorgina labradorica* (Billings), the latter species being referred to *Micromitra (Paterina)*, it is no longer possible to refer Holl's species to *Kutorgina cingulata*, it being clearly congeneric with *Micromitra (Paterina) labradorica*. It differs specifically from that species in a more depressed ventral valve.

The specific name was given in honor of Mr. J. Phillips.

FORMATION AND LOCALITY.—Upper Cambrian: (304g [Holl, 1865, p. 89]) Sandstones of the Hollybush series, Malvern Hills, between Herefordshire and Worcestershire, England.

Lower Cambrian: (304c) "Malvern quartzite" at Raggedstone Hill; and (304d) "Malvern quartzite" at Midsummer Hill; both [Groom, 1902, p. 94] in the Malvern Hills, between Herefordshire and Worcestershire, England.

MICROMITRA (PATERINA) PROSPECTENSIS (Walcott).

Plate II, figures 4, 4a.

Kutorgina prospectensis WALCOTT, 1884, Mon. U. S. Geol. Survey, vol. 8, p. 19, Pl. IX, figs. 1, 1a-b. (Described as a new species. The specimens represented by figs. 1, 1a-b are redrawn in this monograph, Pl. II, figs. 4a and 4, respectively.)

Kutorgina prospectensis WALCOTT, 1886, Bull. U. S. Geol. Survey No. 30, pp. 106-107, Pl. IX, figs. 3 and 3a. (Copies original description and discusses species. Figs. 3 and 3a are drawn from the specimens figured by Walcott, 1884b, Pl. IX, figs. 1a and 1, respectively.)

Kutorgina prospectensis WALCOTT, 1891, Tenth Ann. Rept. U. S. Geol. Survey, p. 610, Pl. LXIX, figs. 4 and 4a. (Mentioned. Figs. 4 and 4a are copied from Walcott, 1886, Pl. IX, figs. 3 and 3a, respectively.)

Iphidea prospectensis (Walcott), SCHUCHERT, 1897, Bull. U. S. Geol. Survey No. 87, p. 234. (Merely changes generic reference.)

Iphidella prospectensis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 307. (Merely changes generic reference.)

Ventral valve subconical, moderately elevated.

Dorsal valve moderately convex, the beak curving down to the posterior margin. The character of the area and pseudodeltidium is unknown. The surface slopes gently from the front to the highest point of the valve and arches down to the point of the beak. There is no trace of a mesial sinus. The cardinal slopes diverge from the beak at an angle of about 170°. Shell substance corneous.

The surface of both valves is marked by clearly defined, regular, concentric striæ that are slightly crenulated by striæ radiating from the beak outward to the margin. The concentric striæ show 10 in a distance of 1 mm. and 8 at the center of the dorsal valve.

Observations.—Nothing is known of the interior or the areas of either valve. The clearly defined concentric striæ, the thick corneous shell, and the long convex pseudodeltidium distinguish the species from all others of the genus known to me, with the possible exception of *Micromitra (Paterina) labradorica swantonensis* (Walcott). In the latter species, however, the striæ are less regular, and present quite a different appearance under the magnifier. In the original description [Walcott, 1884b, p. 19] the comparison was made with *Kutorgina cingulata* (Billings) as to certain points of resemblance between *M. (P.) prospectensis* and the young shells of *K. cingulata*.

This form owes its specific name to its occurrence on Prospect Mountain in the Eureka district, Nevada.

FORMATION AND LOCALITY.—**Lower Cambrian:** (1m and 1p) Limestones of No. 2 of the Silver Peak group, Barrel Spring section [Walcott, 1908f, p. 189], about 2.5 miles (4 km.) south of Barrel Spring and 0.5 mile (0.8 km.) east of the road, in the extreme southeastern corner of the Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County; and (52) arenaceous shales just above the Prospect Mountain quartzite, in a stratigraphic position similar to that of the Pioche shale [Walcott, 1908f, p. 184], at the top of Prospect Mountain, Eureka district [Hague, 1892, Atlas], Eureka County; both in Nevada.

MICROMITRA (PATERINA) STISSINGENSIS (Dwight).

Plate III, figures 1, 1a-e.

Kutorgina stissingensis DWIGHT, 1889, Am. Jour. Sci., 3d ser., vol. 38, pp. 145-147, Pl. VI, figs. 5-8. (Described and discussed as a new species; see below for copy of paragraph on p. 146. The specimens represented by figs. 5, 6, and 8 are redrawn in this monograph, Pl. III, figs. 1c, 1, and 1a, respectively.)

Kutorgina stissingensis DWIGHT, 1891, Trans. Vassar Brothers' Inst. for 1887-1890, vol. 5, pt. 2, p. 105, figs. 5-8, p. 108. (Described and discussed as a new species.)

Iphidea stissingensis (Dwight), SCHUCHERT, 1897, Bull. U. S. Geol. Survey No. 87, p. 234. (Merely changes generic reference.)

Iphidella stissingensis (Dwight), WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 308. (Merely changes generic reference.)

All the specimens of this species known to me are more or less compressed in an argillaceous-arenaceous shale and impure limestone. As far as can be determined the ventral valve is obtusely conical, with the apex slightly incurving.

Dwight [1889, p. 145] in his original description mentions the presence of a distinct false area on the ventral valve, and I find in the two specimens traces of the area, also a wide, low, slightly convex pseudodeltidium.

The dorsal valve appears to have been slightly convex and to have resembled closely the general form and proportions of the same valve of *Micromitra (Paterina) labradorica* (Billings). One somewhat crushed specimen shows a very low false area and a rather broad, low pseudodeltidium somewhat like that of *M. (P.) labradorica*. It is too imperfect, however, for detailed description or illustration.

The surface of both valves is covered with very fine, sharp, slightly crenulated striæ and fine ridges of growth, crossed by very fine radiating striæ and fine radiating undulations of the same type as those in *Micromitra sculptilis* (Meek). The concentric striæ cross the false areas and pass over the pseudodeltidium. Shell substance corneous.

Dwight [1889, p. 146] describes the surface markings in detail as follows:

The concentric ridges are somewhat wavy as seen under a strong magnifier; they are semicircular; a number of those lying nearest to the front margin run out along the upper part of the lateral margins, but the remainder and larger number terminate in regular order along the cardinal border. In front of the central portions of the shell the concentric ridges, which number about 12 to 15 to a millimeter, are regularly concentric; but nearer to the beak the number and the irregularity greatly increase. At a point about one-third the length of the shell from the beak there are 25 or more to the millimeter; as the radiating plications are numerous in this part, there is caused a complexity of curves, which under a powerful magnifier produces the effect of elegant and delicate basketwork. The radiating undulations are very irregular in position and number; they are not thoroughly continuous from the beak in specimens

observed, but appear at irregular intervals singly or in groups; while apt to be crowded around the beak, they are rare near the front margin. On the best specimens about 25 have been counted in the central part of the shell just forward of the beak; had they extended in equal distribution around it, quite to the cardinal border, there would have been about 50. They are also unequal in breadth; where they are somewhat regular, the interspaces about equal the plications in width; these plications are multiplied by implantation.

Observations.—Some young specimens show a surface ornamentation very much like that of *Micromitra sculptilis* (Meek) (Pl. III), but the ornamentation of the adult shell is quite distinct. As stated by Dwight [1889, p. 147], fragments of the shell in the shale might be taken for the shell of "*Lingulepis pinniformis*" (see *Lingulella (Lingulepis) acuminata* (Conrad), p. 545). He also calls attention to the general resemblance to *Micromitra (Paterina) labradorica* (Billings).

Attention has been called under the description of *M. alabamaensis* (Walcott) (p. 337) to the similarity of form and surface ornamentation between that species, *M. (P.) labradorica* (Billings), *M. (P.) labradorica swantonensis* (Walcott), and *M. (P.) stissingensis*.

An apparently identical form occurs at Mount Stephen, British Columbia, in association with *Ogygopsis klotzi* (Rominger). It has the same outline and shows the variations of surface ornamentation so characteristic of *M. (P.) stissingensis* (Dwight) from New York. The radial markings are lightly impressed and are so often entirely obscured that the Mount Stephen form frequently resembles the form described under the name of *Micromitra zenobia* (p. 342).

This form owes its specific name to its occurrence near Stissing, New York.

FORMATION AND LOCALITY.—Middle Cambrian: (367d [Dwight, 1889, p. 145]) Limestone near Stissing, Dutchess County, New York.

A single specimen of a dorsal valve 3 mm. in width, that is apparently identical with shells of similar size from the type locality, occurs at the following locality:

Middle Cambrian: (11m) Drill cores of limestone in the Bonnetterre limestone at horizons 10 and 20 feet (3 and 6 m.) above the Lamotte sandstone, St. Francois County, Missouri.

Apparently identical forms occur at the following locality:

Middle Cambrian: (14s) About 2,300 feet (701 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian, in the *Ogygopsis* zone of the Stephen formation [Walcott, 1908f, p. 210], at the "fossil bed" on the northwest slope of Mount Stephen, above Field, on the Canadian Pacific Railway, British Columbia.

MICROMITRA (PATERINA) STISSINGENSIS ORA n. var.

This form is distinguished from the specimens tentatively referred to *Micromitra (Paterina) stissingensis* on Mount Stephen and from the typical specimens of the latter species in New York by its uniformly larger size and in its distinct radial striation. The Mount Stephen representatives of *M. (P.) stissingensis* frequently betray so little evidence of radial striation that they resemble *Micromitra zenobia*, a form which is associated with *M. (P.) stissingensis ora* and which differs from the latter variety in the entire absence of radial striation. It is possible that the Canadian forms will prove to be distinct from the New York species. Nothing is known of the cardinal area or pseudodeltidium of *M. (P.) stissingensis ora*.

FORMATION AND LOCALITY.—Middle Cambrian: (35k) Shales in the Stephen formation on the west slope of the ridge between Mount Field and Wapta Peak, 1 mile (1.6 km.) northeast of Burgess Pass, above Field, British Columbia.

MICROMITRA (PATERINA) STUARTI Walcott.

Text figures 26A-B, page 355.

Micromitra (Paterina) stuarti WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 58, Pl. VII, figs. 8 and 8a. (Described and discussed as below as a new species. Figs. 8 and 8a are copied on page 355, figs. 26A and 26A'', respectively.)

Ventral valve subconical, with a minute beak arching slightly over a short pseudodeltidium. Cardinal slope with a rounded angle that extends from the beak to the posterolateral margin and defines a very narrow, flattened area on each side of a high triangular fissure that is covered for a short distance at the top by a very short, arched pseudodeltidium.

Dorsal valve rather strongly convex for a species of this genus; the highest part is at about the center of the shell, from whence the slope is very slight to the beak, and rather rapid to the front margin. Beak marginal above a low, broad arching of the posterior margin of the shell; area shown only by a very narrow margin where the shell bends toward the median line; no trace of a pseudodeltidium has been observed.

FIGURE 26.—*Micromitra (Paterina) stuarti* Walcott. A, A', A'', Top, side, and back views of ventral valve, the type specimen (U. S. Nat. Mus. Cat. No. 51485a). B, B', Top and side of dorsal valve (U. S. Nat. Mus. Cat. No. 51485b).

The specimens represented are from Locality 54n, Middle Cambrian limestones in Blacksmith Fork Canyon, east of Hyrum, Cache County, Utah. Figures 26A and 26A'' are copied from Walcott [1908d, Pl. VII, figs. 8 and 8a].

Surface marked by narrow, rounded, concentric threadlike striæ or ridges with short striæ between them. Shell substance corneous.

The average size of adult shells is 8 mm. long by about the same width.

Observations.—This is one of the larger species of the genus. *Micromitra (Paterina) superba* (Walcott) occurs 16 feet (4.5 m.) below and *Micromitra (Iphidella) pannula* (White) 70 feet (21.3 m.) below in the same section.

This fine shell has a short pseudodeltidium much like that of *M. (P.) logani* (Walcott), but it differs in form and greater size; the same is true of *M. (P.) crenistria* (Walcott). It may be closely related to *M. (P.) labradorica utahensis* (Walcott), but the specimens of the latter are too imperfect for close comparison of form.

The specific name is given for my son, Benjamin Stuart Walcott, who assisted me in collecting the specimens during the summer of 1906.

FORMATION AND LOCALITY.—Middle Cambrian: (54n) About 550 feet (167.6 m.) above the Brigham quartzite and 3,640 feet (1,109.5 m.) below the Upper Cambrian, in the limestones forming 2e of the Ute limestone [Walcott, 1908f, p. 197], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

MICROMITRA (PATERINA) SUPERBA (Walcott).

Text figures 27A-B; Plate II, figures 7, 7a-f.

Iphidea cnf.? *ornatella* HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, Pl. IV, figs. 6 and 7. (No text reference.)

Iphidea superba WALCOTT, 1897, Proc. U. S. Nat. Mus., vol. 19, p. 711, Pl. LIX, figs. 1, 1a-c. (Described. The specimens represented by figs. 1, 1a-c are redrawn in this monograph, Pl. II, figs. 7c, 7, 7a, and 7b, respectively.)

Ventral valve subconical, with a minute beak incurving over the pseudodeltidium. Cardinal slope slightly flattened so as merely to indicate an imperfectly defined rather narrow

FIGURE 27.—*Micromitra (Paterina) superba* (Walcott). A, A', Top and back views of ventral valve from Locality 54n, Middle Cambrian limestones in Blacksmith Fork Canyon, Cache County, Utah (U. S. Nat. Mus. Cat. No. 51486). B, Side view of ventral valve showing pseudodeltidium, from Locality 54y, at the same locality but from a slightly lower horizon than that of the specimen represented by figures 27A-A' (U. S. Nat. Mus. Cat. No. 51491).

false area. In some specimens the curvature of the shell is practically continuous to the base of the pseudodeltidium. Pseudodeltidium broad, convex, with its lower margin broadly arched, so as to leave a considerable space between it and the line of the general plane of the shell.

Dorsal valve slightly convex; most elevated a little in front of the small beak which projects a little over the broad open space beneath it. No traces of a false area or pseudodeltidium have been observed.

Surface with rather strong concentric striae, and a few somewhat obscure lines of growth. On the ventral valve the striae extend around to and cross the pseudodeltidium. Shell substance corneous.

Observations.—This is one of the larger species of the genus, being surpassed in size only by *Micromitra (Paterina) labradorica* (Billings). It is clearly distinguishable from *M. (P.) bella* (Billings) by its larger size, more depressed ventral valve, and the form of the pseudodeltidium. The dorsal valves of the two species are quite similar. It differs from *M. pealei* (Walcott) in its broad pseudodeltidium, false area, and surface markings.

One specimen has a length of 9 mm. and a little greater width. The area is vertical, the pseudodeltidium being broken away.

This species is represented by some fine specimens that occur in the lower part of the Middle Cambrian of northern Utah. *Micromitra (Iphidella) pannula* (White) occurs 54 feet (16.5 m.) lower in the section and *M. (Paterina) stuarti* Walcott 16 feet (4.5 m.) higher up.

FORMATION AND LOCALITY.—Middle Cambrian: (74) Sandstone about 300 feet (91.4 m.) above the base of the Tonto group, at the head of Nunkoweap Valley; (74d) sandstone beds in "Tonto" shale, just above massive sandstones near mouth of Bass Canyon, on the south side of the Grand Canyon; and (73a) "Tonto" sandstone in Chuar Valley; all in the Grand Canyon of the Colorado, Arizona.

(54n) About 550 feet (167.6 m.) above the Brigham quartzite and 3,640 feet (1,109.5 m.) below the Upper Cambrian in the limestone forming 2e of the Ute limestone; (54p) about 525 feet (160 m.) above the Brigham quartzite and 3,665 feet (1,127.1 m.) below the Upper Cambrian in the shale forming 2f of the Ute limestone; and (54y) about 510 feet (155.4 m.) above the Brigham quartzite and 3,680 feet (1,121.7 m.) below the Upper Cambrian in the limestones forming 2g of the Ute limestone; all in Blacksmith Fork Canyon [Walcott, 1908f, p. 197], about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

(8j) About 575 feet (175.3 m.) above the unconformable base of the Cambrian in a shale which corresponds in position to shale No. 4 of the Dearborn River section [Walcott, 1908f, p. 202], on the ridge between Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. Geol. Survey), Powell County, Montana.

Specimens that are somewhat doubtfully identified with this species occur in the following locality:

Upper Cambrian: (160) Sandstones forming a remnant of the Gallatin formation, which lies between the exposures of "porphyrite" on the east side of Willow Creek [Peale, 1896, areal geology sheet], 12 miles (19.2 km.) south-southwest of Threeforks, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County, Montana.

MICROMITRA (PATERINA) UNDOSA (Moberg).

Text figures 28A–C.

Kutorgina undosa MOBERG, 1892, Geol. Fören. i Stockholm Förhandl. for 1892, Bd. 14, Hft. 2, p. 112, Pl. III, figs. 10–12. (Described in Swedish as a new species; see below for free translation. Figs. 10–12 are copied in this monograph as figs. 28C, 28A, and 28B, respectively.)

Moberg describes this form essentially as follows:

No specimen shows the umbonal part of the ventral shell completely preserved, yet it seems as if the umbo had projected somewhat beyond the straight hinge margin. From the umbo the shell slopes gently in all directions,

FIGURE 28.—*Micromitra (Paterina) undosa* (Moberg). A, B, Ventral valves. C, Dorsal valve.

The specimens represented by figures 28A and 28B are from Locality 390a, drift blocks of Lower Cambrian sandstone at Stora Rör, Oeland Island; that represented by figure 28C is from Locality 390h, drift blocks of Lower Cambrian sandstone on Nordmannaskär Island; both in Sweden. Figures 28A–C are copied from Moberg [1892, Pl. III, figs. 11, 12, and 10]. Figure 28B may be selected as representing the type specimen.

Judging by the fragments the species must have attained considerable size.

forming a rather feebly convex surface with even arch. The dorsal valve is more flattened and less evenly arched than the ventral and more transverse, with the anterior corners evenly rounded off. The area is not quite distinctly preserved on any specimen; the beak is situated quite near the posterior edge; it is sharply marked and projects with a somewhat blunt point. The ornamentation of the shell is very characteristic; the strongly marked lines of growth appear to be formed of a row of small bows, and on some specimens there are fine, short, sharp, radiating, subordinate, depressed lines. The shell is quite thick, and, it is thought, formed of a hornlike substance.

Two specimens of medium size are 4 mm. and 3.5 mm. long and 5 mm. and 4.75 mm. broad, respectively.

Observations.—This form recalls *Micromitra (Paterina) labradorica* (Billings), which is found in association with *Discinella* at Bic, Canada. The size and character of the shell indicate its relationship to *Micromitra* rather than to *Kutorgina*.

FORMATION AND LOCALITY.—**Lower Cambrian:** With *Discinella* in drift blocks of glauconitic quartzitic sandstone at the following localities [Moberg, 1892b, pp. 112 and 115]; (310f) west of Ekerum; (390a) at several points near *Stora Rör*; (390d) north of Röhälla; and (390h) on Nordmannaskär Island; all in the Kalmar district of the Geological Survey of Sweden, Oeland Island, Sweden.

Moberg [1892b, p. 114] describes some fragments which he refers to *Kutorgina* sp. From his statement that the fragments appear to be of a horny texture it is highly probable that they belong to the genus *Micromitra*.

MICROMITRA (PATERINA) WAPTA Walcott.

Text figures 29A–B.

Micromitra (Paterina) wapta WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 59, Pl. VII, fig. 6. (Described and discussed as below as a new species. Fig. 6 is copied in this monograph as fig. 29A.)

Shell large and thick for a species of this genus. Ventral valve depressed, conical, with the apex above a narrow false area that is outlined by the abrupt curvature of the shell. As the shells usually occur compressed in the siliceous shale, the false area is concealed and the posterior slopes from the apex form a blunt angle at the apex. Dorsal valve transverse, moderately convex, with the posterior margin nearly straight and a little shorter than the greatest width of the valve; beak small, marginal; cardinal slope and false area unknown.

Surface marked by concentric, slightly irregular, rounded lines and ridges of growth that are grouped in bands of varying width; a few radiating striæ or lines occur on the central portions of one ventral valve; with a lens magnifying 20 diameters an occasional roughness can be seen in reflected light on the surface of some of the concentric ridges.

Observations.—This is one of the largest species of the genus. One ventral valve has a length and breadth of 14 mm.; several are 9 to 11 mm. in diameter. It compares in size with *Micromitra (Iphidella) nyssa*, from the same geologic horizon in Montana, but the latter has a reticulate exterior surface of the *M. (I.) pannula* type. It was at first thought that this species might be the old shells of *Acrothele colleni* Walcott, but a careful comparison with the younger stages of growth of *M. (P.) wapta* shows that the latter has only very indefinite traces of the highly ornate surface of *Acrothele colleni* and that the apex of the ventral valve of *M. (P.) wapta* is imperforate and over the posterior margin and not on the general surface of the valve in advance of the margin, as in *Acrothele colleni*. The two species were found associated on Mount Bosworth. *M. (P.) wapta* is of the same type as *M. (P.) labradorica*, *M. (P.) prospectensis*, and *M. (P.) stissingensis*. It differs from all in having more irregular, less definite threadlike concentric lines, and in the manner in which the striæ are assembled in ridges.

The specific name is derived from Lake Wapta, which lies a little to the west of the type locality.

FORMATION AND LOCALITY.—**Lower Cambrian:** (35c) *Drift blocks of siliceous shale supposed to have come from the Mount Whyte formation [Walcott, 1908f, p. 214], found on the south slope of Mount Bosworth, a short distance northwest of the Canadian Pacific Railway track between Stephen and Hector, eastern British Columbia, Canada.*

(35e) About 270 feet (82.3 m.) below the Middle Cambrian, in a greenish siliceous shale correlated with No. 3 of the Mount Whyte formation on Mount Bosworth [Walcott, 1908f, p. 214], in the amphitheater between Popes Peak and Mount Whyte, about 3 miles (4.8 km.) northwest of Lake Louise, southwest of Laggan on the Canadian Pacific Railway, Alberta, Canada.

FIGURE 29.—*Micromitra (Paterina) wapta* Walcott. A, Exterior of ventral valve, the type specimen (U. S. Nat. Mus. Cat. No. 51402a). B, Portion of dorsal valve (U. S. Nat. Mus. Cat. No. 51402b).

The specimens represented are from Locality 35c, a drift block of Lower Cambrian shale on Mount Bosworth, British Columbia. Figure 29A is copied from Walcott [1908d, Pl. VII, fig. 6].

MICROMITRA (PATERINA) WILLIARDI Walcott.

Text figures 30A-E; Plate II, figures 9b-c.

Iphidella major WALCOTT (in part), 1905, Proc. U. S. Nat. Mus., vol. 28, p. 304. (Specimens now referred to *M. (P.) williardi* were included with the specimens representing *M. (P.) major* when this description was written.)

Micromitra (Paterina) williardi WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 60, Pl. VII, fig. 7. (Described and discussed as below as a new species. Fig. 7 is copied in this monograph as fig. 30A.)

Ventral valve subconical, with the apex over the posterior third of the subcircular margin of the valve; false area narrow but clearly defined by a rather sharp angle on the cardinal slopes

FIGURE 30.—*Micromitra (Paterina) williardi* Walcott. A, A', A'', Top, side, and back of a partly flattened ventral valve (U. S. Nat. Mus. Cat. No. 51482a). B, Pseudodeltidium with strong lines and ridges of growth (U. S. Nat. Mus. Cat. No. 51482b). C, Pseudodeltidium with median furrow (U. S. Nat. Mus. Cat. No. 51482c). D, A small dorsal valve (U. S. Nat. Mus. Cat. No. 51482d). E, Enlargement of the outer surface near the front margin of a ventral valve, $\times 15$ (U. S. Nat. Mus. Cat. No. 51482e). Figure 30A represents the type specimen.

The specimens represented are from Locality 56c, 1.125 miles (1.8 km.) northeast of Helena, Shelby County, Alabama. Figure 30A is copied from Walcott [1908d, Pl. VII, fig. 7].

The cast of the interior of the apex of the ventral valve shows a small apical callosity with two radiating grooves extending upward toward the front lateral margin of the shell.

Surface marked by very fine, strong, concentric, elevated striæ that in a specimen 10 mm. in diameter show seven elevated striæ in a distance of 1 mm.; the elevated striæ are crossed by very fine transverse striæ; the elevated striæ cross the false area parallel to its base and arch over the pseudodeltidium.

A ventral valve 10.5 mm. in diameter has a height of 2.5 mm.

Observations.—This species is closely related to *Micromitra (Paterina) superba* (Pl. II). It differs in having a longer pseudodeltidium, more finely elevated striæ on the surface, and a more sharply elevated apex to the ventral valve. It is the Lower Cambrian representative of *M. (P.) superba*.

The specific name is given in honor of Mr. T. E. Williardi, who collected the type specimen.

FORMATION AND LOCALITY.—Lower Cambrian: (17b) Rome ("Montevallo") formation, 4 miles (6.4 km.) south of Helena; and (56c) Rome ("Montevallo") formation, 1.125 miles (1.8 km.) northeast of Helena; both in Shelby County, Alabama.

that breaks the curvature of the shell a short distance from the margin of the pseudodeltidium; pseudodeltidium broad, convex, with its lower margin broadly arched so as to leave a space between it and the general plane of the margin of the shell. Some specimens of the pseudodeltidium are uniformly rounded, in others there is a narrow groove extending from the apex to the base, and on some a very narrow faint ridge is indicated.

Dorsal valve slightly convex, transverse, and slightly rounded at the cardinal margin. No traces of a false area or pseudodeltidium have been observed.

IPHIDELLA Walcott, ^a subgenus of MICROMITRA.

[Iphidea.]

Kutorgina WALCOTT (in part) [not BILLINGS], 1886, Bull. U. S. Geol. Survey No. 30, pp. 101-102. (Genus *Kutorgina* described, but description also includes reference to specimens now referred to *Micromitra*, *Micromitra* (*Paterina*), and *Micromitra* (*Iphidella*.)

Kutorgina HALL and CLARKE (in part) [not BILLINGS], 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, pp. 90-94. (Copies Walcott's description, 1886b, pp. 101-102, and discusses genus, but description and discussion also include reference to specimens now referred to *Micromitra*, *Micromitra* (*Paterina*), *Micromitra* (*Iphidella*), *Protorthis*, and *Billingsella*.)

Iphidea BILLINGS, WALCOTT (in part), 1897, Proc. U. S. Nat. Mus., vol. 19, pp. 707-711. (Discussed. The genus as discussed includes species now referred to *Micromitra*, *Micromitra* (*Paterina*), and *Micromitra* (*Iphidella*.)

Iphidella WALCOTT (in part), 1905, Proc. U. S. Nat. Mus., vol. 28, p. 304. (Merely proposed to replace *Iphidea*, but includes reference to specimens belonging with *Micromitra*, *Micromitra* (*Paterina*), and *Micromitra* (*Iphidella*.)

Iphidea BILLINGS, GRABAU and SHIMER (in part), 1907, North American Index Fossils, vol. 1, p. 201. (Described and includes species referred to each of the subgenera *Paterina* and *Iphidella*.)

Micromitra (*Iphidella*) WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of subgenus.)

Iphidella was proposed to replace *Iphidea*, no species being given as the type. *Micromitra* Meek [1873, p. 479] has priority as the generic name, but as *Iphidella* was intended to include the ornamental crenulated as well as plain type of surface, those species having the former type are now grouped under *Iphidella* as a subgenus of *Micromitra*.

Type.—*Trematis pannulus* White.

The species included in this subgenus and the description of their ornamented surfaces are given under the description of *Micromitra* (p. 336).

MICROMITRA (IPHIDELLA) LOUISE Walcott.

Text figures 31A-B.

Micromitra (*Iphidella*) *louise* WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 56-57, Pl. VII, figs. 4 and 4a. (Discussed as below as a new species. Figs. 4 and 4a are copied in this monograph as figs. 31A and 31B, respectively.)

In form this species is not unlike *Micromitra pealei* (Pl. III, figs. 3, 3a-e) and the more elongate form of *Micromitra* (*Iphidella*) *pannula maladensis* (Pl. IV, figs. 2, 2a-g). It differs from both forms mentioned in its surface characters. In the latter respect it is more like *M. (I.) nyssa* (Pl. III, figs. 9, 9a), but the form of *M. (I.) louise* is more elongate and the apex of the ventral valve is nearer to the posterior margin; the shell also appears to have been thicker. The surface characters are exceedingly minute. Under a glass magnifying twenty diameters the surface looks much like that of the anterior half of Plate IV, figure 1s. The largest ventral valve in the collection has a length of 7.5 mm. and a width of 7 mm.; elevation, 1 mm.

Micromitra (*Iphidella*) *louise* is the oldest known brachiopod from the Cambrian of the Canadian Rocky Mountains. In the Lakes Louise and Agnes section it is 3,150 feet (960.1 m.) below the Middle Cambrian, and 2,760 feet (841.2 m.) below the horizon which is correlated on the basis of the associated faunas with that at which *M. (I.) nyssa* occurs in Montana. It occurs in a fine, hard, dark-gray, siliceous shale in association with *Hyalolithes*, *Cruziana*, and a fragment indicating the free cheek of a trilobite.

FIGURE 31.—*Micromitra* (*Iphidella*) *louise* Walcott. A, Flattened and partly distorted ventral valve, the type specimen (U. S. Nat. Mus. Cat. No. 51401a.) B, Side of laterally compressed ventral valve (U. S. Nat. Mus. Cat. No. 51401b).

The specimens represented are from the Lower Cambrian siliceous Lake Louise shale, at Locality 35d, on the north side of Lake Louise, Alberta, Canada. The figures are copied from Walcott [1908d, Pl. VII, figs. 4 and 4a].

^a The synonymy for this subgenus does not give a complete record of the various genera under which the species now included in *Iphidella* were formerly placed; it includes only those references in which the subgenus is discussed or described. For the sake of completing the record the remaining mere generic references are here listed:

Trematis White [1874, p. 6].

Iphidea Linnarsson [1876, p. 25].

Trematis White [1877, p. 36].

Kutorgina Walcott [1887, p. 190; 1891a, p. 609].

Iphidea Schuchert [1897, p. 234].

Iphidea Matthew [1902b, p. 110].

Iphidea Grönwall [1902, p. 40].

Kutorgina Pack [1906, p. 296].

This form owes its specific name to its occurrence on the shores of Lake Louise.

FORMATION AND LOCALITY.—**Lower Cambrian:** (35d) About 3,150 feet (960.1 m.) below the Middle Cambrian in the siliceous Lake Louise shale [Walcott, 1908f, p. 216] in cliff on the north side of Lake Louise, at its upper end, southeast of Laggan on the Canadian Pacific Railway, Alberta, Canada.

MICROMITRA (IPHIDELLA) NYSSA Walcott.

Plate III, figures 9, 9a.

Micromitra (Iphidella) nyssa WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 57, Pl. VII, fig. 5. (Described and discussed as below as a new species. Fig. 5 is copied in this monograph, Pl. III, fig. 9.)

Ventral valve subcircular in outline, with the posterior margin almost transverse; form depressed, conical, with a minute beak incurving over the pseudodeltidium. The cardinal slope is compressed in all the specimens, but it indicates that there was an imperfectly defined narrow area. Pseudodeltidium, as far as can be determined, broad and short, with its lower margin broadly arched. Dorsal valve slightly convex, beak marginal. No traces of a false area or pseudodeltidium have been observed.

Surface marked by concentric striæ and lines of growth that are crossed obliquely by two sets of fine elevated lines. The crossing of the latter lines forms minute, shallow, rhomboidal pits, which give to the surface the appearance of a fine network. On the ventral valve the striæ cross the pseudodeltidium. Shell substance corneous.

Observations.—This is one of the largest shells of this genus. The ventral valve has a length of 11 mm., width 13 mm. In form it resembles *Micromitra (Paterina) labradorica* (Billings) and in surface characters *M. (Iphidella) ornatella* (Linnarsson) and some varieties of *M. (I. pannula)* (White).

FORMATION AND LOCALITY.—**Middle Cambrian:** (4q) About 315 feet (96 m.) above the unconformable base of the Cambrian and 190 feet (57.9 m.) above the top of the quartzitic sandstones, in a shale which corresponds in stratigraphic position to the upper part of shale No. 6 [see Walcott, 1908f, p. 202], on the ridge between Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. Geol. Survey), Powell County, Montana.

MICROMITRA (IPHIDELLA) ORNATELLA (Linnarsson).

Plate III, figures 6, 6a-d.

Iphidea ornatella LINNARSSON, 1876, Bihang till K. svensk. Vet.-Akad. Handl., Bd. 3, No. 12, pp. 25-26, Pl. III, figs. 42a-e, 43a-c. (Described and discussed in English as a new species; see below for copy.)

Iphidea ornatella Linnarsson, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, pp. 97-98. (Mentioned in discussion of genus *Iphidea*.)

Iphidea ornatella Linnarsson, GRÖNWALL, 1902, Danmarks Geol. Undersøgelse, Række 2, No. 13, p. 40. (Mentioned in Swedish.)

The original description by Linnarsson follows:

Shell small, transversely oval; sides and front rounded; hinge line straight, or nearly so, shorter than the width of the shell; cardinal angles rounded. Surface marked with retiform eminences, including small excavations. The eminences often swell out and become higher at the crossing points, thereby giving to the surface a somewhat granulated appearance (as in fig. 43). In some specimens there are also more or less distinct radiating ridges, especially near the median line of the shell. The shell substance is apparently corneous, but I have not been able to discern more than one layer.

The color in the specimens from Bornholm is black, in those from Westrogothia more brown. Ventral valve convex, subconical. Beak erect and pointed, pierced by a minute round foramen. The posterior, visible only in one specimen, is truncated, so as to form a false area, which has in the middle a triangular fissure, arched over, in the upper part only, by a convex pseudodeltidium. Dorsal valve less convex, somewhat flattened along the middle; greatest height at the beak, which is not, however, so prominent as in the opposite valve. Hinge area not visible in any of the specimens. Interior of both valves unknown. Two specimens measured: Length 3 mm., breadth 4 mm.; and length 2 mm., breadth 3 mm.

Linnarsson [1876, p. 26] speaks of the presence of a minute foramen, but after the study of several finely preserved ventral valves from the *Paradorides* zone of Andrarum, Sweden, I am led to believe that what he considered to be an apical foramen is the minute longitudinal

furrow just in front of the beak, which is shown on the specimens before me and on other species as mentioned in the discussion of the genus *Micromitra* (p. 335). At first sight it is very difficult to determine whether there is an apical foramen or not, but with a strong light and a high power the furrow in *M. (I.) ornatella* is seen to be smooth at the bottom and to show no trace of an opening down through the shell.

The surface ornamentation is of the same type as that of *M. (I.) pannula* (White). It differs in details, but the range of variation in the surface of *M. (I.) pannula* (White) is greater than the differences between its surface and that of *M. (I.) ornatella*.

The most marked distinction between the two species is in the form of the false area and pseudodeltidium of the ventral valve; the dorsal valve of *M. (I.) pannula* also appears to be more elevated. These differences, however, might disappear if we had a large number of specimens of *M. (I.) ornatella* for comparison. With the material we now have they appear to be of specific value.

One specimen from Andrarum shows a narrow area on each side of the wide, low, triangular opening, the pseudodeltidium being broken away. Shell substance corneous.

FORMATION AND LOCALITY.—Middle Cambrian: (8w) Limestones of the *Paradoxides forchhammeri* zone, at Andrarum, 20 miles (32.2 km.) northwest of Simrishamn, Province of Christianstad; (320f) limestone at Andrarum, 20 miles (32.2 km.) northwest of Simrishamn, Province of Christianstad; (320n) limestones of the *Paradoxides forchhammeri* zone at Lovened, Djupadal, 19 miles (30.6 km.) south-southeast of Skara, Province of Skaraborg; and (320y) limestones of the *Paradoxides forchhammeri* zone at Gudhem, 12.5 miles (20.1 km.) south-southeast of Skara, Province of Skaraborg; all in Sweden.

(324c) Shales of Étage 1d [Brøgger] at Krekling, in Sandsvår, Norway.

(16h) Limestones of the *Paradoxides forchhammeri* zone at Borregaard, Bornholm Island, Denmark.

(6g) Limestone near the base of the Middle Cambrian, the lowest horizon carrying *Paradoxides*, northwest side of Chapple Arm Harbor, about 1 mile (1.6 km.) from its head, Trinity Bay, Newfoundland.

MICROMITRA (IPHIDELLA) PANNULA (White).

Text figure 32, page 362; Plate IV, figures 1, 1a-t, 3, 3a.

Trematis pannulus WHITE, 1874, U. S. Geol. Surveys W. 100th Mer., Prelim. Rept., p. 6. (Described as a new species.)
Trematis pannulus WHITE, 1877, idem, Final Rept., vol. 4, pt. 1, pp. 36-37, Pl. I, figs. 4a and 4b. (Described and discussed. The specimen represented by figs. 4a and 4b is redrawn in this monograph, Pl. IV, fig. 1g.)

Kutorgina pannula (White), WALCOTT, 1886, Bull. U. S. Geol. Survey No. 30, p. 105, Pl. VII, figs. 3, 3a; Pl. VIII, figs. 2, 2a-c. (Copies the description and discussion given by White, 1877, pp. 36-37. Pl. VII, figs. 3 and 3a, are drawn from the specimen figured by White, 1877, Pl. I, figs. 4a and 4b. The three specimens represented by figs. 3 and 3a, 2 and 2a, and 2b and 2c are redrawn in this monograph, Pl. IV, figs. 1g, 1j, and 1k and 1p, respectively.)

Kutorgina pannula (White), WALCOTT, 1887, Am. Jour. Sci., 3d ser., vol. 34, p. 190, Pl. I, figs. 14, 14a-b. (Characterized from a new locality. The two specimens represented by figs. 14 and 14a and fig. 14b are redrawn in this monograph, Pl. IV, figs. 1m and 1q and figs. 1k and 1p, respectively.)

Kutorgina pannula (White), WALCOTT, 1891, Tenth Ann. Rept. U. S. Geol. Survey, p. 609, Pl. LXIX, figs. 5, 5a-f. (Mentioned. Figs. 5, 5a, and 5b are copied from Walcott, 1886b, Pl. VIII, figs. 2a, 2, and 2b; figs. 5c, 5e, and 5f from Walcott, 1887, Pl. I, figs. 14, 14b, and 14a; and fig. 5d from Walcott, 1886b, Pl. VII, fig. 3. The six specimens represented by figs. 5 and 5a and 5b-f are redrawn in this monograph, Pl. IV, figs. 1j, 1k, 1m, 1g, 1p, and 1q, respectively.)

Iphidea pannulus (White), SCHUCHERT, 1897, Bull. U. S. Geol. Survey No. 87, p. 234. (Merely changes generic reference.)

Iphidea pannula (White), MATTHEW, 1902, Trans. Roy. Soc. Canada for 1902, 2d ser., vol. 8, sec. 4, No. 3, p. 110. (Characterized from a new locality.)

Iphidella pannula (White), WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 307. (Merely changes generic reference.)

Kutorgina pannula (White), PACK, 1906, Jour. Geol., vol. 14, No. 4, p. 296, Pl. II, figs. 1, 1a-c. (Discussed. Figs. 1b and 1c are outline drawings after Walcott's figures, 1886b, Pl. VIII, figs. 2a and 2b; fig. 1a is an outline drawing after Walcott's figure, 1891a, Pl. LXIX, fig. 5d.)

Iphidea pannulus (White), GRABAU and SHIMER, 1907, North American Index Fossils, vol. 1, p. 201. (Described.)

Micromitra (Iphidella) pannula (White), WALCOTT, 1908, Canadian Alpine Journal, vol. 1, No. 2, p. 244, Pl. I, figs. 1, 1a-c. (No text reference. Figs. 1, 1a-c are copied in this monograph, Pl. IV, figs. 1r, 1e, 1d, and 1q, respectively.)

Ventral valve conical; beak slightly incurving over the pseudodeltidium. Cardinal slopes rounded and flattened so as to form a not very strongly defined false area on each side of the wide, triangular opening, which is crossed toward the summit by a low, highly rounded pseudo-

deltidium; the latter projects directly outward at right angles to the false area and then curves abruptly, so as to be almost flat across the center. A narrow, slight median groove extends from beneath the apex to the posterior margin. Another specimen shows a portion of a pseudodeltidium that is somewhat less elevated than the one described. The apex of the valve just outside of the extreme point of the beak is crossed by a very minute longitudinal depression that is visible only under a strong magnifier.

Dorsal valve slightly convex, sloping regularly from the front margin to the small beak, which is slightly incurved at the margin of the valve. False area clearly defined; in a specimen 10 mm. in width the area has a width of a little over 1 mm. at the side, narrowing to a point at the apex. It is broken midway by a wide triangular opening, which is filled in by a depressed pseudodeltidium. The sides of the deltidium turn in at nearly a right angle for a short distance to the general plane of the pseudodeltidium, which extends across from side to side. Posterior margin slightly arched, and its general surface broken midway by a narrow, distinct groove, which extends from beneath the beak back to the posterior margin. (See Pl.

FIGURE 32.—*Micromitra (Iphidella) pannula* (White). Ventral valve, showing setae, from Locality 35k, Middle Cambrian, Burgess shale member of the Stephen formation, near Field, British Columbia. This specimen is unique in being the first Cambrian brachiopod in which the setae have been observed. The preservation of so frail a portion of the anatomy of the brachiopod is no more remarkable, however, than the presence in the same shales of annelids showing the fringe of setae around the mouth; of crustaceans of many kinds showing the branchiae and appendages; of trilobites with antennae, branchiae, legs, etc.; of holothurians showing the podia and the dental plates; of medusae, sponges, etc.—a fauna which is now being described and figured in volume 57 of the Smithsonian Miscellaneous Collections.

only in the vicinity of the cardinal slopes. The wearing of the surface near the umbo is shown in Plate IV, figure 1m.

In some specimens from Montana (Pl. IV, fig. 1s) the surface is most beautifully preserved, and at first glance there appears to be a specific difference between it and the specimens from Mount Stephen, central Nevada, and the Colorado Canyon. This may be seen by comparing figures 1r and 1s (Pl. IV). There are, however, intermediate forms that possess more or less of the characteristics shown by the two figures. In some specimens there are fine, radiating undulations extending from the apex to the margin that give to the shell an appearance much like that of the young of *M. sculptilis* (Meek) and *M. (Paterina) stissingensis* (Dwight). These are finely shown by Plate IV, figure 1n. The surface ornamentation is much like that of *M. (Iphidella) ornatella* (Linnarsson) of Sweden. It differs but slightly in the form of the depression formed by the union of the crenulated striae.

This species has a wide geographic distribution, and it also occurs both in the Lower Cambrian in the *Olenellus* fauna, and in the Middle Cambrian in the *Olenoides* fauna. Its range in

IV, fig. 1f.) Striae of growth extend across the false areas and pseudodeltidia in both valves; shell substance corneous.

The surface ornamentation of this species is as highly ornamental as that of any Cambrian brachiopod. It appears to be formed of a very fine network of oblique raised lines, which divide it up into minute diamond-shaped pore-like pits, a surface which resembles, under a strong lens, the texture of finely woven cloth. A closer examination, however, of some of the larger shells shows, on the outer margin, crenulated concentric lines, and a little farther back on the shell more deeply crenulated lines; still farther back the points of the crenulations unite so as to form a solid network that gives the appearance of oblique lines crossing at nearly right angles (Pl. IV, fig. 1s).

The surface marking is so strongly characteristic that the presence of the species has been detected a number of times by finding very small fragments of the shell. It not infrequently happens that in old shells the surface characters have been almost entirely worn away, traces of the ornamentation remaining

the West is from Nevada to Montana, and in the Appalachian region from eastern New York to Alabama. At first, on account of its highly ornamented surface, I was led to think that it might belong to a distinct genus from *Micromitra*, but comparisons with *M. sculptilis* (Meek) and the simple ornamentation of *M. (Paterina) bella* (Billings) show transitions in the ornamentation between the otherwise distinct forms.

Varieties of Micromitra (Iphidella) pannula.—In collections from the Middle Cambrian limestones of northern Utah and southern Idaho, material has been selected for illustration which represents varieties of form and surface markings of *Micromitra (Iphidella) pannula* (White) that might be given specific names were it not for the intermediate phases which occur at the same locality with the varieties. The specimens from near Malade, Idaho (Pl. IV, figs. 2, 2a-g), and many not illustrated, show a wide variation in outline and surface. Another series from near Ophir, Utah (Pl. IV, figs. 4, 4a-f), illustrate the entire evolution of the “*pannula*” type of surface, from the concentric striæ to the fine network of oblique, raised lines dividing the surface into minute, diamond-shaped depressions. In some of the examples from Malade the ridges are so sharp and clear that the surface has a honeycomb-like appearance (Pl. IV, fig. 2g).

The surface of *M. (I.) pannula* (White) is composed of porelike pits formed by obliquely crossing, elevated lines (Pl. IV, figs. 1n-1s), and for convenience of reference the forms showing variations from this may be separated into the varieties *maladensis* and *ophirensis* (pp. 364-365).

FORMATION AND LOCALITY.—**Upper Cambrian:** (96) Limestones near the ford on the Cedartown road, 1.5 miles (2.4 km.) south of Rome, Floyd County, Georgia.

Middle Cambrian: (14s) About 2,300 feet (701 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian, in the *Ogygopsis* zone of the Stephen formation [Walcott, 1908f, p. 210], at the “fossil bed,” on the northwest slope of Mount Stephen, above Field on the Canadian Pacific Railway; (57j) about 2,000 feet (609.6 m.) above the Lower Cambrian in the limestones forming 2 of the Stephen formation [Walcott, 1908c, p. 237 (6)], just east of the “fossil bed” on the northwest slope of Mount Stephen, above Field on the Canadian Pacific Railway; (58j) about 1,900 feet (579 m.) above the Lower Cambrian near the base of the limestone forming 2 of the Stephen formation [Walcott, 1908c, p. 238 (7)]; on the east side of Mount Stephen about 3,000 feet (914 m.) above the Canadian Pacific Railway track, 3 miles (4.8 km.) east of Field; and (35k) Burgess shale member of the Stephen formation on the west slope of the ridge between Mount Field and Wapta Peak, 1 mile (1.6 km.) northeast of Burgess Pass, above Field; all in British Columbia.

(57g) About 1,700 feet (518 m.) above the Lower Cambrian and 3,250 feet (991 m.) below the Upper Cambrian in the siliceous shales forming 2d of the Stephen formation [Walcott, 1908f, p. 211], on Mount Bosworth, north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide between British Columbia and Alberta, Canada.

(4q and 4q') 315 and 310 feet (96 and 94.5 m.), respectively, above the unconformable base of the Cambrian and 190 and 185 feet (57.9 and 56.4 m.), respectively, above the top of the quartzitic sandstones in shales and limestones which correspond in position to the upper part of shale No. 6 of the Dearborn River section [see Walcott, 1908f, p. 202], on the ridge between Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. Geol. Survey), Powell County; (302t) limestone northeast of Logan, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County; and (149a) limestone at the forks of Pole Creek, above Cherry Creek basin, Threeforks quadrangle (U. S. Geol. Survey), Madison County; all in Montana.

(55c and 163)^a Spence shale member of the Ute limestone [Walcott, 1908a, p. 8], about 50 feet (15.2 m.) above the Brigham quartzite and 2,755 feet (839.7 m.) below the Upper Cambrian, in a ravine running up into Danish Flat from Mill Canyon; and (59f) limestones immediately underlying the Spence shale member of the Ute limestone [Walcott, 1908a, p. 8], in a saddle north of the creek which flows into Mill Canyon from the west; both about 5 miles (8 km.) west-southwest of Liberty and 15 miles (24.2 km.) west of Montpelier, Bear Lake County, Idaho.

(5b and 54s) Dark blue-gray Langston limestone [Walcott, 1908f, p. 198] just above the Cambrian quartzitic sandstones, north side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

(31v) 650 feet (198 m.) above the Lower Cambrian and 3,750 feet (1,143 m.) below the Upper Cambrian, in shales at the top of the limestone forming 1a of the Howell formation [Walcott, 1908f, p. 182], northeast side of Dome Canyon, about 4 miles (6.4 km.) west-southwest of Antelope Springs; and (31s) 490 feet (149.4 m.) above the Lower Cambrian and 3,925 feet (1,196.3 m.) below the Upper Cambrian, in the pinkish, argillaceous shale forming 1d of the Howell formation [Walcott, 1908f, p. 182], south side of Dome Canyon, about 1 mile (1.6 km.) below the divide and 3 miles (4.8 km.) west-southwest of Antelope Springs; both in the House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.

(14t) Limestone lying on the slope between the Cambrian quartzite and the massive blue limestone 100 feet (30.5 m.) above, Mount Nebo Canyon, 3 miles (4.8 km.) southeast of Mona, Juab County; (55u) limestones about 200

^a This species also occurs in Locality 55e.

feet (61 m.) above the Lower Cambrian [see Walcott, 1908f, p. 171], 0.25 mile (0.4 km.) below the Maxfield mine, in Big Cottonwood Canyon, on the west front of the Wasatch Mountains southeast of Salt Lake City, Salt Lake County; (30a) shale on the north side of Big Cottonwood Canyon, 1 mile (1.6 km.) below Argenta, in the Wasatch Mountains southeast of Salt Lake City, Salt Lake County; and (541) about 500 feet (152.4 m.) above the Brigham quartzite and 3,700 feet (1,127.8 m.) below the Upper Cambrian in the Spence shale member of the Ute limestone [Walcott, 1908f, p. 197], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County; all in Utah.

(31) Shales at the Chisholm mine; and (333 [Pack, 1906, p. 296]) shales at the Abe Lincoln mine; both on the southwest slope of the Ely Mountains, 3 miles (4.8 km.) northwest of Pioche, Lincoln County, Nevada.

(73a) "Tonto" sandstone in Chuar Valley; and (74) sandstone about 300 feet (91.4 m.) above the base of the Tonto group, at the head of Nunkowēap Valley; both in the Grand Canyon of the Colorado, Arizona.

(14) Limestones overlying the sandstones of the Rome formation, near the wagon road and in a quarry near the railroad track, 7 miles (11.2 km.) southwest of Rome, Floyd County, Georgia.

(101) Rogersville shale, just above the road in the hill west of the schoolhouse, 3.5 miles (5.6 km.) southwest of Rogersville on the road to Melinda Ferry [Keith, 1896a, areal geology sheet], Hawkins County, Tennessee.

Lower Cambrian: (57r and 58s) About 150 feet (46 m.) below the Middle Cambrian near the base of the limestones forming 3 of the Mount Whyte formation [Walcott, 1908c, p. 241 (10)]; and (35f)^a about 300 feet (91 m.) below the Middle Cambrian in the limestone forming 6 of the Mount Whyte formation [Walcott, 1908c, p. 242 (11)]; both just above the tunnel on the north shoulder of Mount Stephen, about 3 miles (4.8 km.) east of Field, British Columbia, Canada.

(41) Limestone in the Pioche shale [Walcott, 1908a, p. 11], on a ridge 2.5 miles (4 km.) northwest of the town of Cherry Creek, White Pine County; (30) limestone 8 miles (12.8 km.) north of Bennetts Spring, on the west slope of the Highland Range, Lincoln County; and (31a) limestone interbedded in the Pioche shale [Walcott, 1908a, p. 11], just above the quartzite on the east side of the anticline, near Pioche, Lincoln County; all in Nevada.

(34) Limestone on roadside a little west of the bridge over Poultney River at Low Hampton, about 5 miles (8 km.) east-northeast of Whitehall, Whitehall quadrangle (U. S. Geol. Survey), Washington County; (38a) limestone 2 miles (3.2 km.) south of North Granville, on the road which turns south from the road running between that village and Truthville, 4 miles (6.4 km.) west-northwest of Granville, Fort Ann quadrangle (U. S. Geol. Survey), Washington County; and (44b) limestone near North Chatham in the northern part of the Kinderhook quadrangle (U. S. Geol. Survey), Columbia County; all in New York.

(4v) About 200 feet (61 m.) above the unconformable base of the Cambrian and 75 feet (22.9 m.) above the top of the quartzitic sandstones in a shale which corresponds in stratigraphic position to shale No. 6 of the Dearborn River section [Walcott, 1908f, p. 202], Gordon Creek, 6 miles (9.6 km.) from South Fork of Flathead River, Ovando quadrangle (U. S. Geol. Survey), Powell County, Montana.

Specimens that are somewhat doubtfully referred to this species occur at the following localities:

Middle Cambrian: (55c) Spence shale member of the Ute limestone [Walcott, 1908a, p. 8], about 50 feet (15.2 m.) above the Brigham quartzite, and 2,755 feet (839.7 m.) below the Upper Cambrian, in a ravine running up into Danish Flat from Mill Canyon, about 6 miles (9.6 km.) west-southwest of Liberty and 15 miles (24.2 km.) west of Montpelier, Bear Lake County, Idaho.

(54a) A drift block supposed to have come from the horizon of Locality 32x, a horizon correlated with the shales forming 2d of the Bloomington formation in Blacksmith Fork Canyon [Walcott, 1908f, p. 195], in Wasatch Canyon, east of Lakeview ranch, about 5 miles (8 km.) north of Brigham, Boxelder County, Utah.

(13k) Shales of Matthew's [1903, p. 15] Coldbrook, above the great falls in Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia.

MICROMITRA (IPHIDELLA) PANNULA MALADENSIS (Walcott).

Plate IV, figures 2, 2a-g.

Iphidella pannula maladensis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 306. (Characterized as a new variety.)

Surface covered with elevated, sharp, distinct ridges that give it an irregular, honeycomb-like appearance.

This form owes its varietal name to its occurrence near Malade, Idaho.

FORMATION AND LOCALITY.—Middle Cambrian: (5b) Dark blue-gray Langston limestone [Walcott, 1908b, p. 198] just above the Cambrian quartzitic sandstones, on the north side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

(6g) Limestone near the base of the Middle Cambrian, the lowest horizon carrying *Paradoxides*, northwest side of Chapple Arm Harbor about a mile (1.6 km.) from its head, Trinity Bay, Newfoundland.

^a This species is somewhat doubtfully identified from this locality.

MICROMITRA (IPHIDELLA) PANNULA OPHIRENSIS (Walcott).

Plate IV, figures 4, 4a-f.

Iphidella pannula ophirensis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 306. (Characterized as a new variety.)

Surface formed by raised, concentric lines and ridges that inosculate and become more and more irregular until the typical surface of *Micromitra (Iphidella) pannula* is developed.

This form owes its varietal name to its occurrence at Ophir, Utah.

FORMATION AND LOCALITY.—**Middle Cambrian:** (3e) Thin-bedded limestones less than 400 feet (121.9 m.) above the quartzitic sandstones of the Cambrian, near Ophir, Oquirrh Range, Tooele County, Utah.

Shells that I can not separate from this variety occur at the following localities:

Middle Cambrian: (3x) About 2,200 feet (670.6 m.) above the Lower Cambrian and 2,200 feet (670.6 m.) below the Upper Cambrian, in the limestone forming 1d of the Marjum limestone [Walcott, 1908f, p. 180], 2.5 miles (4 km.) east of Antelope Springs, in ridge east of Wheeler Amphitheater; and (11o) about 2,750 feet (838.2 m.) above the Lower Cambrian and 1,650 feet (502.9 m.) below the Upper Cambrian, in limestone at the base of 1a of the Marjum limestone [Walcott, 1908f, p. 179], about 4 miles (6.4 km.) southeast of Antelope Springs, in the spur at the junction of the Deseret and Swasey Spring roads; both in the House Range [Walcott, 1908i, Pl. XIII], Millard County, Utah.

(54s) Dark blue-gray Langston limestone [Walcott, 1908f, p. 198], just above the Cambrian quartzitic sandstones, on the north side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

(14s) About 2,300 feet (701 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian, in the *Ogygopsis* zone of the Stephen formation [Walcott, 1908f, p. 210], northwest slope of Mount Stephen, above Field on the Canadian Pacific Railway, British Columbia, Canada.

Fragments of shells that are not to be separated by their surface characters from *Micromitra (Iphidella) pannula ophirensis* occur in China. The fragments also indicate that the shells were about the same size and form.

Middle Cambrian: (C5) Lower limestone member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 39], 3.2 miles (5.1 km.) southwest of Yenchuang, Sintai district, Shantung, China.

Genus VOLBORTHIA von Möller.^a

Volborthia VON MÖLLER, 1874, Neues Jahrb. für Mineralogie, pp. 449–452. (Described and discussed in German as a new genus; see below for free translation of description on pp. 449–451.)

Acrotreta (Volborthia) (von Möller), OEHLERT, 1887, Manuel de conchyliologie, by Fischer, p. 1266. (Described in French as a subgenus, with figures of "*Acrotreta (Volborthia) recurva* (Kutorga).")

Volborthia von Möller, HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York for 1891, p. 249. (Described.)

Volborthia von Möller, HALL and CLARKE, 1892, Forty-fifth Ann. Rept. New York State Mus. for 1891, p. 565. (Copy of preceding reference.)

Volborthia von Möller, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, pp. 95–96. (Original description, von Möller, 1874, pp. 449–451, translated essentially as below and genus discussed.)

Volborthia von Möller, WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of genus.)

The description in substance by von Möller [1874, pp. 449–451] is as follows:

The shells remind one in their form of a broad horn whose opening is closed through a very convex cover (the dorsal valve). Seen from above, the outline of the figured shell, in consequence of the rounded edges and the likewise rounded front edge, is transversely oval. Only the posterior edge, whose length is about one-half of the breadth of the shell, appears straight.

The ventral valve is very high, conical, and has a strong, recurved, prominent beak without any perforation. Between the beak and the hinge line (posterior edge) is a distinctly marked and high three-cornered area, whose length is divided by a narrow ridge extending from the beak to the middle of the straight hinge line.

The dorsal valve is convex, nevertheless decidedly lower than the ventral, and it has just such a beak as the other. Although this beak lies in the same vertical line with that of the opposite valve, it nevertheless touches the hinge line of the shell, without any area lying between.

The surface of both valves is smooth and covered only with very fine concentric growth striæ, which extend without interruption also over the area of the ventral valve. On the latter they appear much coarser and not so regular, especially on the ridge where these striæ are rather strongly bent downward toward the beak of the ventral valve.

Neither the ventral nor the dorsal valves appear to have inward projections; at least the casts (molds) show not the slightest traces thereof. Likewise the muscle scars are not known, and on the casts are usually found only a small

^a Prior to the definition of *Volborthia* by von Möller [1874, p. 449] the species now referred to this genus was placed under *Acrotreta* Kutorga [1848, p. 277].

number of widely separated radial lines. As regards the substance of the shell, it must be remarked that it is exactly the same as in the genus *Siphonotreta*, i. e., calcareous-horny, and of a brown color. Under the microscope, enlarged six to eight times, the valves show a fine but distinct puncturing, invisible to the unaided eye.

As regards the dimensions of the shell, the largest examples have a length of 14, a breadth of 19, and a thickness of 16 mm., while the height of the ventral valve is 10 mm.

Hall and Clarke [1892c, p. 96] compare this genus with *Kutorgina* on account of the general form and surface characters, and call attention to the presence of an areal ridge similar to that of "*Iphidca*" = *Micromitra*. The authors were under the impression that an apical foramen existed in *Micromitra* and probably in *Volborthia* and that the areal ridge was the "eurved" foramen scar. I do not find a foramen in *Micromitra*, and none has been seen in *Volborthia*. The areal ridge appears to be the arched pseudodeltidium, both in *Micromitra* [Pl. III, fig. 3b] and *Volborthia* [Pl. I, fig. 6e].

The previously published illustrations of *Volborthia recurva* do not show any opening between the posterior margins of the valves, but that there was an opening for the passage of the pedicle is shown in figures 33A and 33A'.

The absence of defined muscle scars and vascular markings is a characteristic of this genus. The generic name was given in honor of Dr. A. von Volborth.

Type.—*Acrotreta recurva* Kutorga.

VOLBORTHIA RECURVA (Kutorga).

Text figures 33A–B; Plate I, figures 6, 6a–e.

Acrotreta recurva KUTORGA, 1848, Verhandl. Russ.-kais. min. Gesell. St. Petersburg for 1847, No. 12, pp. 277–278, Pl. VII, figs. 9a and 9d. (Characterized and discussed in German as a new species. The description of Pl. VII gives the name of the species as "*Acrotreta incurva*." The only figures accompanying the reference are those mentioned, 9a and 9d.)

FIGURE 33.—*Volborthia recurva* (Kutorga). A, Posterior view of specimen figured by von Möller, 1874, Pl. VII, figs. 1–6. A', Enlargement of same to show pedicle opening, light from the right. B, Posterior view of an associated ventral valve showing crenulation of the striae on the false area.

The specimens represented are from Locality 336g, limestone in the vicinity of Zarskoe Selo, Russia. The specimens are now in the museum at Reval, but a cast of the type specimen represented in figures 33A–A' is in the collections of the U. S. National Museum, Cat. No. 58298.

Volborthia recurva (Kutorga), VON MÖLLER, 1874, Neues Jahrb. für Mineralogie, pp. 449–452, Pl. VII, figs. 1–6. (The description and discussion of the species is included in that of the genus, which is in German and which is translated on pp. 355–356. Figs. 1–6 are copied in this monograph, Pl. I, figs. 6, 6a–e, respectively. The specimen represented by figs. 6, 6a–e of von Möller's paper is redrawn in this monograph, figs. 33A–A'.)

Volborthia recurva (Kutorga), HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York for 1891, figs. 261 and 262, p. 249. (No text reference. Figs. 261 and 262 are copied from von Möller 1874, Pl. VII, figs. 2 and 6, respectively.)

Volborthia recurva (Kutorga), HALL and CLARKE, 1892, Forty-fifth Ann. Rept. New York State Mus. for 1891, figs. 261 and 262, p. 565. (Copy of preceding reference.)

Volborthia recurva (Kutorga), HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, pp. 95–96, figs. 52 and 53. (The description of the species is included in that of the genus, which is translated, essentially as on pp. 355–356 of this monograph, from von Möller, 1874, pp. 449–451. Figs. 52 and 53 are copied from von Möller, 1874, Pl. VII, figs. 2 and 6, respectively.)

The generic description includes the important characters of this, the only known species.

FORMATION AND LOCALITY.—Ordovician: (336g [Kutorga, 1848, p. 278]) Limestone in the vicinity of Zarskoe Selo; and (337j [Fr. Schmidt, personal communication, 1908]) zone BIII α or BIII β , characterized by *Asaphus raviceps*, a little above the zone with *Asaphus expansus*, at Obuchow (Obokhov), on Wolchow River; both in the Government of St. Petersburg, Russia.

Genus **HELMERSENIA** Pander.

- Siphonotreta* JEREMEJEV, 1856, Verhandl. Russ.-kais. min. Gesell. St. Petersburg for 1855-6, No. 2, pp. 73 and 80. (New species *S. ladogensis* described in German.)
- Helmersenian* PANDER, 1861, Bull. Acad. imp. sci. St.-Petersbourg, vol. 3, columns 48-49. (Jeremejew's species described and discussed in German.)
- Helmersenian* PANDER, ZITTEL, 1880, Handbuch der Palæontologie, Bd. I, Abth. 1, p. 666. (Described in German.)
- Keyserlingia* KARPINSKY, 1887, Bull. Acad. imp. sci. St.-Petersbourg, vol. 31, p. 476, footnote. (The use of *Keyserlingia* in this footnote is clearly a typographical error, *Helmersenian* being intended. The genus is discussed in German.)
- Helmersenian* PANDER, OEHLERT, 1887, Manuel de conchyliologie, by Fischer, p. 1264. (Described in French, see p. 369.)
- Helmersenian* PANDER, HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York for 1891, p. 254. (Described.)
- Helmersenian* PANDER, HALL and CLARKE, 1892, Forty-fifth Ann. Rept. New York State Mus. for 1891, p. 570. (Copy of preceding reference.)
- Helmersenian* PANDER, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 119. (Copies Hall and Clarke, 1892a, p. 254, and discusses genus.)
- Helmersenian* PANDER, WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of genus.)

General form longitudinally ovate, subcircular to transversely ovate, with the ventral valve broadly subacuminate and dorsal valve broadly rounded except at the minute beak; ventral valve moderately convex, rising on the umbo and sloping most rapidly down to the minute, nearly marginal beak; dorsal valve gently convex with apex marginal.

The interior of the ventral valve shows a narrow area with a thickened median ridge extending a short distance forward to the visceral area. The latter has the general form of the visceral area of *Obolus*, with the muscle scars in front on each side of the center. One specimen shows the central and the outside and middle lateral scars; beneath the area, at the base of the median ridge, the main vascular sinuses arch outward and then forward; between the vascular sinus and the outer margin of the shell there are indications of the transmedian and anterior lateral muscle scars. The interior of the dorsal valve shows a slender median ridge extending well forward into the valve, and the main vascular sinuses well out toward the side of the shell. None of the specimens show the muscle scars of this valve, and I have not been able to find more than the broken margin of the area.

Surface marked by concentric striæ and a few stronger lines of growth. Scattered irregularly over the surface on the epidermal layer there are elongate bases of numerous slender spines that closely resemble the bases of the spines of *Siphonotreta verrucosa* (Eichwald). The inner surface is minutely punctate with a few larger scattered punctæ.

The shell varies in size from 2 to 3 mm. in diameter. It rarely exceeds 2 mm.

Type.—*Siphonotreta ladogensis* Jeremejew.

From Pander's remarks [1861, p. 48] in describing the genus *Helmersenian* it is evident that he considered the shells described by Jeremejew [1856, p. 73] as *Siphonotreta ladogensis* as belonging to this genus. As pointed out by Karpinsky [1887, p. 476] the form studied by Pander differs from *S. ladogensis* in being more circular in outline. I strongly suspect, however, that if the types of *S. ladogensis* were compared with the material used by Pander they would be found to be specifically identical. The figures given by Jeremejew [1856, p. 73] in my opinion represent young shells of the form subsequently named by Karpinsky.

Through the courtesy of Dr. Fr. Schmidt, of the Geological Survey of Russia, I have had the opportunity of studying specimens of *Helmersenian* collected by Karpinsky at Kunitz, in the Government of Pskow. I also received from Dr. A. Mickwitz some fine specimens collected at Koporje, in the Government of St. Petersburg. With the specimens from Kunitz there somewhat rarely occurs *Keyserlingia buchi* (de Verneuil) and large numbers of *Obolus* (*Schmidtia*) *celatus* Volborth. The associated forms at Koporje are *Obolus* (*S.*) *celatus* and fragments of a larger *Obolus*.

Pander [1861, p. 48] describes the ventral valve of this species as having at the top of the beak a circular opening that does not, as in the "*Siphonotretum*," extend into a canal. I have carefully studied with a strong lens more than one hundred specimens of the ventral valve of

this species, and in only three specimens have I found what might be considered to be a perforation at the apex of the shell. In one of these it was clearly a circular fracture of the shell, and in the other two the apex had been pushed in so as to form a small circular depression with sharp edges. Several interiors of the shell also fail to show any indication of an opening through the shell; the specimen illustrated by Pander [1861, Pl. II, fig. 2b] and the enlargement (g) are very much like the specimen with the minute circular opening caused by fracture. There are several other specimens in which there is a slight depression just in advance of the beak, which indicates that the shell was very thin and slightly flexible at this point. I would not venture to suggest that this was an imperfect ventral valve were it not for the fact that I have such an abundant supply of material which is clearly to be referred to the form described by Pander. I would further state that it frequently occurs that the apex of the shell is slightly raised above the surface so as to form a minute node and that when the apex is pushed in the edge of the depression follows a concentric line of growth.

If we consider that *Helmersenia* is not a perforate shell, it then falls in with *Obolus* except that the area of the ventral valve is unlike that of *Obolus* and it has a spinose outer surface. The area, as illustrated by Pander [Pl. LXIII, fig. 7d], is of the *Mickwitzia monilifera* type (Pl. VI, fig. 1''). The shells of *Helmersenia* are delicate and much more like those of *Mickwitzia* than *Obolus*. The outer surface of *Mickwitzia* is not known to be spinose, but if we compare the surface shown by figures 1n and 2 (Pl. VI) with figures 7, 7a-b (Pl. LXIII) of *Helmersenia* we gain an impression of their great similarity. On account of the character of the area of the ventral valve, the appearance of the shell, and its surface, *Helmersenia* is placed within the Paterinidæ.

The generic name was given in honor of Grégoire de Helmersen.

HELMERSENIA LADOGENSIS (Jeremejew).

Plate LXIII, figures 7, 7a-f.

- Siphonotreta ladogensis* JEREMEJEW, 1856, Verhandl. Russ.-kais. min. Gesell. St. Petersburg for 1855-6, No. 2, pp. 73 and 80, figs. 5a-c, p. 73. (Described in German on p. 80, as a new species.)
- Discina buchii* EICHWALD (in part) [not (DE VERNEUIL)], 1860, Lethæa rossica, ancienne période, vol. 1, sec. 2, p. 914. (Includes *Siphonotreta ladogensis* with *Discina buchii*.)
- Helmersenia* PANDER, 1861, Bull. Acad. imp. sci. St.-Petersbourg, vol. 3, columns 48-49, Pl. II, figs. 2a-g. (Described and discussed in German. Figs. 2d and 2f are copied in this monograph, Pl. LXIII, figs. 7d and 7c, respectively.)
- Helmersenia jeremejewi* DALL, 1877, Bull. U. S. Nat. Mus. No. 8, p. 31. (See the text below for discussion of this reference.)
- Keyserlingia panderi* KARPINSKY, 1887 (April), Bull. Acad. imp. sci. St.-Petersbourg, vol. 31, p. 476, footnote. (Discussed in German; see below.)
- Helmersenia jeremejewi* DALL, OEHLERT, 1887 (June), Manuel de conchyliologie, by Fischer, p. 1264. (Mentioned in French as type of genus; see below.)
- Helmersenia* sp.? PANDER, HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York for 1891, p. 254, Pl. IV, figs. 6 and 7. (Mentioned in the text, which is a description of the genus. Figs. 6 and 7 are copied from Pander, 1861, Pl. II, figs. 2d and 2b, respectively.)
- Helmersenia* sp.? PANDER, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 119, Pl. IV, figs. 4 and 5. (Mentioned. Figs. 4 and 5 are copied from Hall and Clarke, 1892a, Pl. IV, figs. 6 and 7, respectively.)

The specific description of this species has been included in the generic description.

Pander [1861, p. 48] gave no specific name to the form which he described as *Helmersenia*, but he refers to *Siphonotreta ladogensis* Jeremejew in such a manner as to indicate that he considered that species as the type.

In 1877 Dall published a list of the names applied to the subdivisions of the Brachiopoda, and [1877, p. 31] designated the type species as *Helmersenia jeremejewi*, ascribing the species to Pander and referring to page 47 of Pander's paper. Pander [1861, p. 48] places the words "*Siphonotreta* Jeremejew" after *Helmersenia*, refers to the place of publication of *Siphonotreta? ladogensis* Jeremejew, and discusses the generic relations of the specimens before him with *Siphonotreta ladogensis*. It is thus evident that Pander did not name the species *H. jeremejewi*.

Dall tells me that he did not see Jeremejew's paper in which the specific name *ladogensis* was proposed.

Ten years later Karpinsky [1887, p. 476], in his report on the Geology of the Government of Pskow, gives a list of the species occurring in the *Ungulite* sandstone and places a footnote after the word *Helmersenia*, in which he refers to "*Keyserlingia*" and suggests that the species be called "*Keyserlingia panderi*." In this footnote he mentions "*Keyserlingia*" three times, but places after the first a reference to Pander's description of *Helmersenia*. It is evident that Karpinsky intended to specifically identify *panderi* with *Helmersenia* and not *Keyserlingia*.

A few months after the appearance of Karpinsky's paper Oehlert, in Fischer's *Manuel de Conchyliologie*, describes the genus *Helmersenia* [1887, p. 1264] and gives as the type *H. jeremejewi* Pander. He gives no reference, but it is likely that he followed Dall.

This form owes its specific name to its occurrence near Ladoga, near St. Petersburg, Russia.

FORMATION AND LOCALITY.—Upper Cambrian: (336o) Ungulite grit, Kaporje, Government of St. Petersburg; (336p) Ungulite grit, Kunitz, Government of Pskow; and (336q [*Jeremejew, 1856, pp. 73 and 80*]) *Ungulite sandstone, near Ladoga, Government of St. Petersburg*; all in Russia.

Superfamily OBOLACEA Schuchert.

Family CURTICIIDÆ Walcott and Schuchert.

Genus CURTICIA Walcott.

Curticia WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 319. (Mentioned as below as a new genus.)

Curticia WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 143. (Classification of genus.)

The description of the type species, *Curticia elegantula*, includes all that is known of this genus.

The generic name is given in recognition of the excellent work of Dr. Cooper Curtice, of Moravia, New York, both as a field collector and laboratory assistant.

CURTICIA ELEGANTULA Walcott.

Plate I, figures 2, 2a-1.

Curticia elegantula WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 319-320. (Described and discussed as below as a new species.)

General form subcircular, biconvex. Surface of exterior of shell marked by fine, concentric, slightly undulating striæ, and lines and varices of growth. When the thin exterior layer is exfoliated, the inner layers are ornamented by numerous fine, radiating lines, very much as in *Dicellomus* and *Obolus*, also by more or less imbricating concentric lines. The inner surface shows radiating and concentric lines without the visceral area. Shell substance corneous and probably calcareous. The shell is built up of a thin, outer, surface layer and several inner layers or lamellæ, slightly oblique to the outer surface on the umbo and central parts of the valves. The lamellæ are more oblique and numerous toward the front and sides, and thus thicken the shell over those parts. The average ventral valve has a length of 5 mm.; width, 6 mm.; dorsal valve, 5 mm. by 5 mm.

Ventral valve strongly convex, most elevated at the umbo, and arching over to a minute, slightly incurved apex; area rudimentary, with a high, triangular, open delthyrium occupying most of it. A cast of the interior of the valve shows that a narrow, elevated ridge occurs just in advance of the apex, and a very small visceral area is indicated.

Dorsal valve evenly convex, apex marginal; cardinal area rudimentary, narrow, and divided by a low, broad, open delthyrium. The interior shows a median ridge and septum, with small rounded depressions beneath the umbo on each side of the median ridge and a little in advance of the apex. Ventral muscle scars small and clearly defined. Anterior lateral scars small and situated in advance of the central scars close to the median ridge and at its anterior extremity. Main vascular sinuses broad and slightly defined.

Observations.—This shell was labeled by the field collector as *Dicellomus politus*. In external form it resembles that species, but the open delthyrium of the ventral valve and the

absence of an area on the dorsal valve distinguish it. It appears to be a form intermediate in development between *Rustella*, with its absence of cardinal areas and its very rudimentary pedicle aperture, and *Obolus*, with its well-defined cardinal areas with their pedicle grooves. It occurs in large numbers and its dark smooth shell is a very striking object in the buff-gray sandstone.

FORMATION AND LOCALITY.—Upper Cambrian: (82b) "St. Croix sandstone" along the railroad track near Taylors Falls, Chisago County, Minnesota.

Family OBOLIDÆ King.

Subfamily OBOLINÆ Dall.

Genus OBOLUS Eichwald.^a

- Obolus* Eichwald, WALCOTT, 1908, *Smithsonian Misc. Coll.*, vol. 53, No. 4, Pl. XI, and pp. 142 and 144. (Classification of genus.)

Diagnosis (mainly after Mickwitz [1896]).—Shells nearly equivalve, equal-sided, moderately convex, subcircular, transversely or longitudinally ovate, in some species subtriangular or subrectangular.

Shell substance calcareoconeous, structure foliated; the layers of calcium phosphate alternating with homogeneous, horny lamellæ are traversed by microscopic canals, which in their main direction are perpendicular to the plane of stratification; the inner layers and lamellæ are more or less oblique to the thin outer layer over the central and posterior portions of the valves, and strongly so with the short lamellæ of the anterior and lateral parts. Surface shining as if varnished, with concentric and usually radial striation, varying from bare visibility to deeply incised concentric folds and radial ribs. Color of shell dark grayish blue to black, when in a state of decomposition dark reddish brown to whitish. Front and side margins usually thin, sharp-edged, fragile, lying in the same plane with the hinge margin, which is greatly thickened inside. Area mainly in the plane of the edge of the valve, in the ventral valve triangular, owing to the somewhat projecting beak, in the dorsal valve rounded at the point,

in both striated parallel to the base, and traversed, from the point of the beak on, by the more or less diverging lines of folding of the areal lamellæ and a strongly marked pedicle furrow.

Visceral area (splanchnocœle) on the ventral valve restricted to the back part, in the dorsal valve drawn far forward into the vascular area (brachiocœle) and strongly indented laterally; in both valves it extends backward up close to the base of the visceral (splanchnocœlic) part of the area, which is bounded by the flexure line (folding of the area lamellæ). The edge of the mantle of the beak part is restricted to the side areas (pleurocœles), appearing between the flexure lines of the area lamellæ.

Anterior part of the thickened posterior half of valve slopes down to the middle of the valve, forming in the ventral valve a line concave to the beak, in the dorsal valve a sinus. The lateral parts of the thickening are drawn out into thin side edges. In front of the base of the area is a small median septum, which in the dorsal valve for the most part is less prominent, but in both is often hardly perceptible by reflected light as an almost invisible crest. Beginning at the median septum, there are in each valve two gradually deepening grooves for the main vascular canals, which intersect the thickened part parallel to the edge of the shell. In the dorsal valve these grooves combine with the sinus from the calcareous ridge in forming two projections pushing themselves like horns into the middle of the valve. The traces of the main vessels of the mantle lobes in the continuation of the visceral (splanchnocœlic) vascular grooves are subparallel and project into the vascular (brachiocœlic) parts of the valves, in the ventral valve terminating with their anterior ends in the peripheral vascular canal, in the dorsal valve, shortly before reaching the vascular canal, bending about into the interior of the shell, and vanishing at the scars of the anterior lateral muscles. The peripheral vascular canals in both valves run along their edge from one side area (pleurocœle) to the other. Traces of secondary vessels radiate in great number from the grooves of the main vessels toward the peripheral canals and into the middle of the shell.

In the median line of the ventral valve, between the median septum and the anterior edge of the thickened part of the shell, there is a deep, heart-shaped pit, with its point directed forward and having a shallow median groove. In the cavity of the dorsal valve there is a more or less pronounced median ridge, extending into the anterior part of the valve and divided longitudinally by a shallow median furrow.

On each valve there are six pairs of muscular scars, and in the ventral valve in front of the pedicle furrow there is the unpaired scar of the pedicle muscle. The umbonal scars are close to the base of the area, in the ventral valve divided, inclosing the scar of the pedicle muscle between them, in the dorsal valve confluent in the median line of the valve. The scars of the central pair of muscles are placed about centrally in both valves; in the dorsal one they are isolated on the inner sides of the ends of the hornlike projections; in the ventral valve they are united with the scars of the outside and middle lateral muscles, on both sides of the anterior part of the heart-shaped pit. The transmedian muscles are undivided; their scars in both valves are close to the base of the area in the line of prolongation of the flexure lines. The anterior lateral muscle scars of the ventral valve adjoin the transmedians, overlapping them a little on the outside; in the dorsal valve they are isolated, pushed far forward toward the frontal margin and situated at the anterior end of the median crest separating them. The scars of the second pair, the middle lateral muscles, in the ventral valve are combined with those of the central and outside lateral muscles at the point of the heart-shaped pit; in the dorsal valve they blend with those of the outside lateral muscles and lie against them on the inner sides of their anterior ends. Finally the scars of the third pair, the outside lateral muscles, in the ventral valve are combined with those of the central and middle lateral muscles and lie on the outer sides of the former, while in the dorsal valve they are united with those of the middle lateral muscles and lie obliquely outward before the scars of the transmedian muscles. In both valves the parietal band closely circumscribes all muscle scars externally, crossing the furrows of the main vessels and entering the visceral (splanchnocœlic) part of the area at its base on a line with the flexure lines.

The study of a series of the interior of the ventral valve of *Obolus apollinis* (Pl. VII) shows that the arrangement of the point of attachment of the middle (k) and outside (l) laterals and

central muscle scars (h) varies considerably in the different specimens. Mickwitz's diagrammatic figure shows the middle lateral scars (k) to be the smaller and situated close to the median line. This, however, is not the case in all specimens. In Plate VII, figure 9, the middle lateral (k) is the larger and the two other scars are arranged quite differently from those in Mickwitz's diagrammatic figure. In Plate VII, figure 5, the growth of the shell has crowded all three of the muscle scars so that they are arranged in transverse lines. In Plate VII, figure 4, they occur up on the side of the visceral cavity (v), the central scars (h) occupying the greater portion of the space, the outside laterals (l) being crowded forward, and the middle laterals (j), which are so large in figure 9, are scarcely to be determined at the inner angle in figure 4. In Plate VII, figure 3, the points of attachment of the scars are on a ridge, and they present no points of similarity to the position assigned in the diagrammatic figure of Mickwitz, nor to the positions in Plate VII, figures 9, 4, and 5. The points of attachment are sunk deep into the ridge, and on this account it is impracticable to distinguish between the central (h) and middle lateral (k) scars. In figure 1 the scars are also on a high ridge. They are slightly depressed and apparently range very much as in Plate VII, figure 5, except that the middle laterals (k) are nearer the median line. It does not appear to be possible to distinguish the centrals.

Type.—*O. apollinis* Eichwald.

Observations.—It is stated by Hall and Clarke [1892c, p. 339] that Mickwitz did not obtain his results from the type specimens of *Obolus apollinis*, but from a hitherto undescribed form, *Obolus quenstedti*. This is true [see Mickwitz, 1890, p. 60, footnote], but in his final work [1896, p. 128] Mickwitz diagnoses the genus and cites *Obolus apollinis* as the type. He says [1896, p. 25]:

A more accurate study of the greatly increased material has convinced me that *O. quenstedti* can not be maintained as a species, since it is merely the terminal link of a series of variations which, like var. *maximus* and *ingricus*, can be traced back to *O. apollinis*. Thus, the typical species remains *O. apollinis* Eichwald.

Mickwitz [1896] has given in his exhaustive memoir on *Obolus* a very complete historical sketch and full description of the genus and its subgenera so far as known to him. The study was conducted with such care and thoroughness and the material was so well preserved that our present knowledge of the adult shell of *Obolus* is nearly as complete as that of the adult shell of the recent *Lingula*. The student is referred to the memoir of Mickwitz for the literature, history, and geology of the Cambrian formations of the eastern Baltic region of Russia, for a minute description of the external and internal characters of the shells of the Baltic species of *Obolus* and of the relations of *Obolus* to *Lingula* and *Obolella*, and for detailed observations on *Obolus* and its subgenera as known to him.

Obolus and Lingula.—After studying the species from American rocks and a very good series from the typical localities in Russia, I am not prepared to agree with Mickwitz that *Obolus* should be referred to the Lingulidæ. In figure 34 the interior of the valves of *Obolus* and *Lingula* may be compared.

The points of similarity between *Obolus* and *Lingula*, as described by Mickwitz, are:

1. Chemical constitution and microscopic structure.
2. Position of the umbonal muscle in the dorsal valve.
3. Arrangement of the vessels of the circulatory system. Mickwitz [1896, p. 121] says:

Issuing between the same muscle scars (j-l, h in the ventral valve; l, i, k-h in the dorsal valve) from the splanchnocœle, two main vessels extend in each valve into the fore part of the mantle lobes and branch inward and outward into numerous secondary vessels. The only difference in the arrangement of the vessels consists in this, that in *Lingula* the main vessels of the two valves empty into the peripheral canal, while in *Obolus* this takes place only in the large valve. In the dorsal valve the main vessels, shortly before reaching the peripheral canals, bend into the interior of the valves and end at the scars of the anterior lateral muscles.

4. General arrangement of the muscle scars. These are essentially the same, the points of difference being of a generic character.

The points of difference between the two genera are:

1. The areas of the valves.
2. Attachment of the pedicle muscle. In *Lingula* the muscle is attached back of the scar of the umbonal muscle of the ventral valve, whereas in *Obolus* it is situated between the divisions of the scar of the umbonal muscle of the ventral valve.
3. Bipartition of certain muscles. Mickwitz says [1896, pp. 118-121]:

Besides the somewhat unlike arrangement of some scars, to which we shall presently return, the bipartition of certain muscles constitutes the most characteristic difference in the internal organization of the two genera. The umbonal muscle of *Obolus*, which is divided in the ventral valve [gg, fig. 34A], is undivided in *Lingula* [g, fig. 34C] while conversely the two transmedian muscles of *Lingula* [ii, fig. 34C], one of which is divided throughout its length, are represented in *Obolus* by a pair of undivided muscles [i, fig. 34A].

The position of the umbonal muscle is the same in the two genera; at most it is somewhat crowded away from the base of the area in *Lingula*, because of the pedicle muscle. On the contrary, the transmedian muscles, besides their bipartition, present other differences. In *Obolus* the scars of that pair of muscles on the ventral valve are combined with those of the anterior lateral muscles [j, fig. 34A], while in the corresponding shell of *Lingula*, though lying in a similar position, they are separated from the anterior lateral muscles. With the dorsal valves the case is reversed. *Obolus* shows the scars of the pair of muscles in question isolated [i, fig. 34B], while in *Lingula* they are united with those of the middle and outside lateral muscles [i, k, and l, fig. 34D].

The scars of the two last-named muscles on the dorsal valve of *Obolus* [k and l, fig. 34B] are combined in a manner analogous to those of *Lingula*, so that the whole difference in the arrangement of the scars in question (aside from the bipartition of one transmedian muscle in *Lingula*) consists in the reversal of their combination. In *Obolus*, on the ventral valve, the scars i and j are united, in *Lingula* they are separated; in *Lingula*, on the dorsal valve, i, k, and l are united, while in *Obolus* they are separated.

The scars of the anterior lateral muscles of the dorsal valve have a closely similar position in the two genera, except that in *Obolus* they are moved farther forward and are separated by the median ridge (p), while in *Lingula* they are nearer to the center of the valve and are united [j, fig. 34D].

The other scars of the lateral muscles on the ventral valve of *Obolus* also are quite analogous in their position to the corresponding scars in *Lingula* [k, l, fig. 34C]. True, in their case also small displacements and changes of form occur, but yet I am unable to attach to these any special value. The two genera show the scars of the outside lateral muscles [l, figs. 34A and 34C] combined with those of the central muscles [h, figs. 34A and 34C], but we have seen that in some species of the genus (*O. triangularis*, *O. panderi*, and some species of the subgenus *Schmidtia*) the first-named scars are separate from those of the central muscles and change their subtriangular form, being drawn out backward into a rounded form, more like that in *Lingula*. The scars of the middle lateral muscles (k) of the ventral valve, on the contrary, are only in Eichwald's genus combined with those of the central muscles (h), while in *Lingula* they are separated. It is probable, however, that some species of the above-named subgenus share this peculiarity with *Lingula*.

Finally, the scars of the central muscles of the two genera differ merely by their somewhat different form in the ventral valve and by their somewhat different position to the axis of symmetry on the dorsal valve. It was pointed out, however, in speaking of the central muscles of *Obolus* that the backward-protracted points of the subtrapezoidal scars in the ventral valve of the typical species (as well as those of the outside lateral muscles) are lacking in the species of the subgenus *Schmidtia*, so that even in regard to form there is an agreement with *Lingula*. In the dorsal valve of *Obolus* the elliptic scars of the central muscles are parallel to the major axis of the valve or somewhat converging behind [h, fig. 34B], while in *Lingula* they are strongly convergent anteriorly [h, fig. 34D].

To the altered position of the muscle scars in *Obolus* corresponds the modified form of the parietal band. The latter in both valves of *Lingula* is rhombic, but in the dorsal valve it is drawn farther forward than in the ventral [fig. 34D].

In *Obolus* the parietal band on the dorsal valve extends still farther toward the frontal edge than in *Lingula*, and in its posterior part is more markedly bent inward from both sides, producing a characteristic unequally three-lobed figure [fig. 34B]. The parietal band of the ventral valve of *Obolus* on the contrary is subelliptical in form, and rather approaches that of *Lingula*.

More important than this difference in form of the splanchnocœle is the difference in the form of the mantle lobes which is manifest from the position of the posterior part of the parietal band. In *Lingula* the parietal band is moved away from the base of the area and thus constitutes a narrow space between the two pleurocœles, which space is occupied by the mantle lobes that extend around the entire beak part of the valves. These mantle lobes of the beak are in the dorsal valve also covered with mantle bristles, while the border of the mantle of the ventral valve in the splanchnocœlic part of the area (deltidium, King) is free from bristles [fig. 34C]. In *Obolus* on the contrary the posterior part of the parietal band is close to the base of the splanchnocœlic part of the area, whose lamellæ, as we have seen, are bent up at right angles to the plane of the valve and therefore could not have been deposited by mantle lobes resting against the valves. Hence the mantle lobes of *Obolus* extended only as far as the pleurocœles, and were lacking, as well as the mantle bristles, in the splanchnocœlic part of the area of both valves. At that point there was only the muscular wall of the body connecting the two valves, from which the pedicle emerged.

I think that the differences pointed out are sufficient to distinguish *Obolus* as of distinct family relations from *Lingula*, but I must at the same time admit that the transitions from *Obolus* to *Lingulella* and from *Lingulella* to *Lingula* are so clearly indicated that it is only by a somewhat arbitrary decision that species of *Lingulella* like *L. bella* (Pls. XIX and XXXVI) can be referred to the Obolidæ. Schuchert [1893, p. 360] creates the family Lingulellidæ for *Lingulella* and allied forms.

Obolus and *Obolella*.—Authors have compared *Obolella* with *Obolus*, and Mickwitz [1896, p. 129] thought that they might possibly be congeneric. The discovery of a pedicle opening at the beak of the ventral valve of *Obolella* places the latter with the Acrotretidæ.

Criteria of subgenera.—The criteria upon which the subgenera of *Obolus* have been founded are largely based on the form of the outline of the valves, character of outer surface, thickness of shell, and, to a more limited extent, the muscular and vascular markings on the interior of the valves. I was at first inclined to give considerable weight to the position of the sinuses occupied by the main vascular canals, but further study showed such a gradation in the various species that efforts to use the character in subgeneric classification were abandoned. The following table illustrates some of the variations in the position of the vascular sinus, and many more may be found in the figures of *Obolus* and its subgenera than are indicated in the table below:

Variation in the position of the vascular sinus of *Obolus* and its subgenera and *Lingulella*.

Subgenera of Obolus.—*Acritis* Volborth [1869, p. 212] is ornamented with concentric lines which are elevated, irregular, and undulating. The valves are strongly arched and massive; the visceral area (splanchnocœle) small and short, and the pedicle furrow conical and deeply impressed in the cardinal area. Type: *Obolus* (*Lucina*) *antiquissimus* Eichwald (Pl. XIII, fig. 3, and Pl. XV, figs. 1, 1a-c).

Bröggeria Walcott [1902, p. 605] has the typical ovate outline of *Obolus*, but differs from *Obolus* and its other subgenera in having a very deep visceral depression (splanchnocœle) in both valves, and in its minutely papillose interior surface. Type: *Obolella salteri* Holl (Pl. XIII, figs. 1, 1a-n, and Pl. XV, figs. 4, 4a-d).

Eoobolus Matthew [1903, p. 135] was proposed for certain species of *Obolus* in which the central muscle scars and anterior scars were arranged in a more or less quadrate manner, as in *Obolus selwyni* (Matthew) (Pl. XXXVI, figs. 2a and 2b). I find that the specimen illustrated by Matthew [1903, Pl. VIII, fig. 2d] was distorted. It is figured in Plate XXXVI of this monograph (fig. 2a), and a second distorted specimen in figure 2b. A more perfect specimen is illustrated in figure 1g, and the changes in position of the muscle scars in the center of the dorsal valve may be seen by comparing Plate XXXVI, figures 2a and 1g; Plate XXXVII, figure 1c; Plate XXVIII, figures 1h and 1g; Plate XXXI, figure 6e; Plate XVII, figures 1h and 1j; Plate XXI, figure 2a. A study of the figures cited and many others shows that the position of the central muscle scars and anterior lateral scars is not a character of sufficient importance and value upon which to found a subgenus of *Obolus*. On this account *Eoobolus* is considered as a synonym of *Obolus*.

Euobolus Mickwitz [1896, p. 314] was elaborately described as a subgenus of *Obolus* by Mickwitz, who referred to it all species showing radial striation. He says [1896, p. 128]:

In grouping the species by their distinctive marks, two great divisions become apparent. One of them shows, besides the concentric striation of the outer surface of the shell, peculiar to all *Obolus* species, also a radial striation which is lacking in the others. Thus, while the concentric striation is a general characteristic, which, nevertheless, by differences in development, furnishes useful specific features, the radial striation, due to a different condition of the edge of the mantle (no matter whether this be due to the mantle bristles or to the circulatory vessels), constitutes a group character. For this reason all radially striated *Oboli*, whose other characters also show a certain agreement in other respects, were united into a subgenus *Euobolus*. Furthermore, the concentric striae of certain species showed remarkable variations, which also indicate a peculiar organization of the edge of the mantle. The species *O. siluricus* and *antiquissimus* show this striation running parallel on the growth lamellæ corresponding to a period of vegetation,

while in all other *Obolus* species they converge. As the species mentioned differ from each other considerably in other respects, it seemed to me necessary to assign them to special subgenera, *Thysanotos* and *Acritis*. The remaining species also fall into two groups differing from each other in many ways, one of them, *Schmidtia*, approaching more the typical *Obolus*, the other, *Leptembolon*, being closer to *Lingula*.

The delimitation of the species presents similar difficulties to those in the allied genus *Lingula*. The differences are manifest, but are difficult to express in words. This is true especially of some species of the subgenera *Euobolus* and *Schmidtia*.

The introduction of the subgenus *Euobolus* for the radially striated *Oboli* does not appear to be necessary for a proper classification of the genus. If the radially striated species are considered to be the typical form of *Obolus*, then those differing from it to a sufficient degree may be referred to a subgenus. The genus *Lingulella* has only radially striated forms included within it, and this in part includes species that otherwise would be referred to *Euobolus*. To this extent *Euobolus* is a synonym of *Lingulella*.

I have endeavored to identify in material from the typical localities the varieties of *Obolus* and its subgenera described by Mickwitz, but find it practically impossible in nearly all cases. They may be found of value to the special student, but they are not of service in studies of the Cambrian fauna. Such minute discriminations would lead to an endless amount of detailed description if followed in the study of the faunas as they occur in the collections before me.

Fordinia Walcott [1908d, p. 64] includes specimens that have a *Lingulella*-like outline, with the development of a tendency to form a platform or thickening in the valves. Type: *Obolus* (*Fordinia*) *perfectus* Walcott.

Leptembolon Mickwitz [1896, p. 199] is referred to in this monograph as a subgenus of *Lingulella*.

Lingulepis Hall [1863, p. 129] is referred to in this monograph as a subgenus of *Lingulella*.

Lingulobolus Matthew [1895b, p. 260] is a *Lingulella*-like form, with a thick, strongly arched shell and surface marked by subimbricated wavy concentric lines. Type: *Lingulella?* *affinis* Billings (Pl. XVI, figs. 1, 1a-e).

Mickwitzella Walcott [1908d, p. 70] is an *Obolus* with strong, uniformly curved concentric striae, with the lamellae of growth fringed along their anterior (external) edges. Type: *Obolus* *siluricus* Eichwald (Pl. XV, figs. 1, 1a-c).

Monobolina Salter [1866b, p. 334] has been referred to as a subgenus of *Obolus* by Matthew [1902b, p. 98]. It differs from *Obolus* in having a platform in the ventral valve of the same type as that of *Elkania* (Pl. LI, figs. 1, 1a, and 4b) and is clearly not descendant from *Obolus* or generically connected with it. Salter [1866b, p. 334] placed *Monobolina* as a section of the genus *Obolella* Billings.

Palæobolus Matthew [1899, p. 201] shows concentric lines which are elevated and slightly irregular. The visceral area (splanchnocœle) is large and elongate, and the main vascular canals are close to the visceral area (Pl. XXXII, figs. 5, 5a-g). The surface of *Palæobolus* is of the same type as that of *Acritis*, but the visceral cavity and vascular canals differ materially in the two forms. Type: *Palæobolus bretonensis* Matthew.

Schmidtia Volborth [1869, p. 208] is a *Lingulella*-like shell without radial striation. All the species are small and as the concentric striation is very fine the shell surface is nearly smooth. Type: *Schmidtia celata* Volborth (Pl. XIV, figs. 1, 1a-c).

Westonia Walcott [1901, p. 691] is a *Lingulella*-like form distinguished by peculiar, transverse, semi-imbricating, "ripple-embossed" lines that cross both the concentric and radiating striae. Type: *Lingula aurora* Hall (Pl. XLVI).

Stratigraphic range of Obolus and subgenera.—*Obolus* has a stratigraphic distribution ranging from the limits of the *Olenellus* fauna, through the Middle Cambrian or *Olenoides* fauna and the Upper Cambrian or *Dikellocephalus* [*Olenus*] fauna, into the base of the Ordovician fauna. *Obolus* proper has not been found below the upper portion of the Lower Cambrian. The youngest species of the genus are the largest, and also have certain strongly marked characteristics which

have grouped them under the subgenus *Lingulobolus*. The species referred to *Obolus* from the Lower Cambrian include *Obolus prindlei* (Pl. XXVII, figs. 3, 3a-e) which is intermediate in form between *Obolus apollinis* (Pl. XIV, figs. 6, 6a) and the type species of the genus *Lingulella*, *L. davisii* (Pl. XXXI, figs. 6e, 6f). *Obolus smithi* (p. 416) is a typical form of *Obolus*, while *Obolus parvus* (p. 408) is a minute form of which only the exterior is known.

Of the 77 species and 11 varieties from the Cambrian referred in this memoir to *Obolus* and its subgenera, 4 species occur in the Lower Cambrian, 46 species and 5 varieties in the Middle Cambrian, 43 species and 7 varieties in the Upper Cambrian, and 10 species in the passage beds between the Cambrian and Ordovician. From the Ordovician 23 species are described. (See table of species, pp. 110 and 113.)

Acritis is represented in the Upper Cambrian of Russia by the type species. A species is doubtfully referred to it from Nevada.

Bröggeria is represented by one species. This is found in the Upper Cambrian and the passage beds to the Ordovician of the North Atlantic province of Europe and eastern North America.

Fordinia includes species from the Middle and Upper Cambrian of Utah and Nevada.

Lingulobolus is represented by two species occurring in the Lower Ordovician rocks of Newfoundland and in conglomerate pebbles in Massachusetts.

Mickwitzella is confined to one species identified from the passage beds between the Upper Cambrian and the Ordovician of Russia.

Palæobolus is represented by a single species from the Middle Cambrian of Nova Scotia.

Schmidtia is represented in the Upper Cambrian "*Obolus*" sandstones of Russia by four species, which form a peculiar and restricted local group.

Westonia has its greatest development in the Middle Cambrian, where thirteen species and one variety occur. Six species are known from the Upper Cambrian, one from the passage beds to the Ordovician, and five in the lower portion of the Ordovician.

Geographic distribution of Obolus and subgenera.—In Europe *Obolus* proper appears to be limited to the type area in northwestern Russia, where it reaches its greatest development, and to a few limited localities in Bohemia and Sweden. Its subgenera, especially *Westonia*, have a wide distribution, the latter having been found in Russia, Bohemia, many localities on the Scandinavian Peninsula, England, and China.

Only one form is known from Sweden—*O. schmalenseei* (Walcott). The genus (or one of its subgenera) appears to be present in the Cambrian of Argentina, and four species have been described from eastern China—*O. chinensis* (Walcott), *O. minimus* Walcott, *O. obscurus* Walcott, and *O. shansiensis* Walcott. It is on the North American continent that *Obolus* reaches its greatest development outside of its original localities in Russia. It is widely distributed and often occurs in great numbers at favorable localities. It occurs along the lines of the Appalachian Range from Newfoundland, Cape Breton, and New Brunswick to Tennessee. It is represented in the northern Mississippi Valley region, in the isolated uplifts of Cambrian rocks in the Black Hills of South Dakota, the Ozark Mountains of Missouri, the Llano Hills of central Texas, and westward in Wyoming, Montana, Utah, and Nevada.

Of the species in this memoir that are placed under *Obolus* from Bohemia, *O. feistmanteli* (Barrande) and *O. complexus* Barrande are probably true representatives of the genus, but the following species are exceedingly doubtful in their generic identification:

- Obolus* ? *advenus* Barrande.
- Obolus* ? *ancillus* (Barrande).
- Obolus* ? *bavaricus* (Barrande).
- Obolus* ? *minor* Barrande.
- Obolus* ? *mirandus* (Barrande).
- Obolus* ? *palliatus* Barrande.
- Obolus* ? *rokitzanensis* Barrande.

This is true also of the two forms from Sardinia: *Obolus* ? *zoppi* Walcott, and *O.* ? *meneghini* Walcott.

The species of the genus and its subgenera recognized by Mickwitz [1896] in Russia are:

OBOLUS ACADICUS Walcott.

Plate XI, figure 5.

Obolus acadica WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 324-325. (Characterized and discussed as below as a new species.)

Only interiors of the dorsal valve of this species occur in the collections made by Loper on McNeil Brook in 1900. The material was provisionally referred to *Lingulella concinna* Matthew, but the broadly rounded subquadrilateral form of the dorsal valve seems to distinguish it from that species and also from *Obolus* (*Palæobolus*) *bretonensis* (Matthew).

The visceral area is narrow, extending a little in advance of the center of the valve. The main vascular trunks are narrow and widely separated. They belong to the submarginal group and are thus quite unlike those of *O. (P.) bretonensis*. The exterior surface and ventral valve are unknown.

The specific name is derived from Acadia, the original name for Nova Scotia, in which the species occurs.

FORMATION AND LOCALITY.—Upper Cambrian: (3h) Shale and shaly limestone on McNeil Brook, 1.5 miles (2.4 km.) east of Marion Bridge, eastern Cape Breton, Nova Scotia.

OBOLUS? ADVENUS Barrande.

Plate XII, figures 5, 5a-b.

Obolus? advena BARRANDE, 1879, Systême silurien du centre de la Bohême, vol. 5, pt. 1, Pl. XCV, figs. iv: 1-2. (No text reference. Figs. 2A, 1A, and 2B are copied in this monograph, Pl. XII, figs. 5, 5a-b, respectively.)

This species is known to me only by the figures of Barrande [1879b, Pl. XCV, fig. iv] some of which are copied on Plate XII. The species is of the same type as *O. complexus* Barrande, so far as the means of comparison permit us to judge. It occurs at the same relative geologic horizon as *O. complexus*.

FORMATION AND LOCALITY.—Lower Ordovician: (303d [Barrande, 1879b, Pl. XCV]) Étage dI, Swarow, Bohemia, Austria-Hungary.

OBOLUS ANCEPS Walcott.

Plate X, figures 3, 3a-f.

Obolus anceps WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, pp. 388-389. (Described and discussed as below as a new species.)

General form broadly ovate, somewhat subcuneate. Valves moderately convex. Surface marked by fine lines of growth, and finer slightly undulating concentric striae; when the outer layer is exfoliated the outer surface of the inner layer is marked by very fine, radiating striae and numerous lines of growth; the inner surface of the shell is nearly smooth, judging from a

partial cast in the limestone. The shell is relatively thin and formed of a very thin outer layer and one or more thin inner layers or lamellæ, which thicken the shell from the umbonal region and toward the front and sides.

A cast of the interior of a dorsal valve that is referred to this species shows that a strong median ridge was present; also a median septum and a strong main vascular sinus. The area is short and marked by rather prominent flexure lines, as indicated by the flexures in the transverse lines of growth.

Observations.—This species might be taken for the young of *O. matinalis* (Hall) or *O. mæra* (Hall and Whitfield), were it not for the great difference in the thickness of the shell. It occurs at a slightly higher horizon at the base of the Pogonip limestone.

FORMATION AND LOCALITY.—Lower Ordovician (63) Limestone at the base of the Pogonip limestone northeast of Adams Hill, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

Upper Cambrian: (61) Limestone in the Dunderberg shale [Walcott, 1908f, p. 184], a little south of the Hamburg mine, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

OBOLUS? ANCILLUS (Barrande).

Plate XII, figure 2.

Lingula ancilla BARRANDE, 1879, Systême silurien du centre de la Bohême, vol. 5, pt. 1, Pl. CXI, fig. vi: 3. (No text reference. Fig. 3 is copied in this monograph, Pl. XII, fig. 2.)

This is a small shell of which we have only the one figure given by Barrande [1879b, Pl. CXI, fig. vi: 3] from which to express an opinion as to its generic relations. The configuration of the valve and the lamellose character of the shell, as indicated by the portions adhering to the cast, are what has led me to make the provisional reference to *Obolus*. There are no interior characters shown in the figure.

FORMATION AND LOCALITY.—Lower Ordovician: (303g [Barrande, 1879b, Pl. CXI]) Étage d1, at Rabenberg, Bohemia, Austria-Hungary.

OBOLUS APOLLINIS Eichwald.

Text figures 4 and 15, page 299; Plate VII, figures 1–8, 10–17; Plate XIV, figures 6, 6a.

Obolus apollinis EICHWALD, 1829, Zoologia specialis, vol. 1, p. 274, Pl. IV, figs. 5a–b. (Described in Latin as a new species.)

Ungula plana PANDER, 1830, Beiträge zur Geognosie des russischen Reiches, pp. 59 and 163, Pl. XXVIII, figs. 3a–b, 5a–b. (Characterized in German on p. 59; description of plate on p. 163.)

Ungula plana or *convexa* PANDER, 1830, idem, p. 163, Pl. XXVIII, figs. 2a–b. (Only the description of the plate occurs on p. 163.)

Ungula rotunda PANDER, 1830, idem, pp. 59 and 163, Pl. XXVIII, figs. 4a–b. (Characterized in German on p. 59; description of plate on p. 163.)

Ungula ovata PANDER, 1830, idem, pp. 59 and 154, Pl. III, fig. 23 (not Pl. XXVIII, figs. 6a–b, referred to *Obolus* (*Schmidtia*) *celatus*). (Characterized in German on p. 59; description of plate on p. 154.)

Ungula transversa PANDER (in part), 1830, idem, pp. 59 and 163, Pl. XXVIII, figs. 7a–b, 8a–b? (not Pl. III, fig. 24, which represents a specimen of *Obolus apollinis quenstedti*). (Characterized in German on p. 59; description of plate on p. 163.)

Ungula triangularis PANDER, 1830, idem, pp. 59, 154, and 163, Pl. III, fig. 25, Pl. XXVIII, figs. 9a–b. (Characterized in German on p. 59; descriptions of plates on pp. 154 and 163.)

Obolus apollinis EICHWALD, 1840, Jour. Natur- und Heilkunde Medizinischen Akad. St. Petersburg, pts. 1 and 2, p. 167. (Not seen.)

Orthis unguia VON BUCH, 1841, Archiv für Mineralogie, Bd. 15, Hft. 1, pp. 7–8, Pl. II, fig. 9. (Described and discussed in German, as belonging with the “*Unguliten*.”)

Obolus apollinis EICHWALD, 1843, Beiträge zur Kenntniss des russischen Reiches, Bd. 8, No. 2, p. 140. (Discussed in German.)

Obolus apollinis Eichwald, DE VERNEUIL (in part), 1845, Géologie de la Russie d'Europe, by Murchison, de Verneuil, and de Keyserling, vol. 2, pt. 3, pp. 290–292, Pl. XIX, figs. 3a–d. (Described and discussed in French; see Matthew, 1892, pp. 43–44, for translation. De Verneuil includes *Obolus apollinis ingricus*, *Obolus* (*Acritis*) *anti-quissimus*, and *Obolus* (*Mickwitzella*) *siluricus* in this species.)

Obolus apollinis Eichwald, KUTORGA, 1848, Verhandl. Russ.-kais. min. Gesell. St. Petersburg for 1847, No. 12, pp. 251 and 252. (Discussed in German.)

Aulonotreta polita KUTORGA (in part), 1848, idem, pp. 279–282, Pl. VII, figs. 10a–f. (Described and discussed in German as a new species. The text includes *Obolus apollinis*, *Obolus apollinis ingricus*, and *Obolus* (*Mickwitzella*) *siluricus*.)

- Obolus apollinis* Eichwald, MORRIS, 1849, Annals and Mag. Nat. Hist., 2d ser., vol. 4, p. 316. (Merely changes generic and specific reference of Kutorga's *Aulonotreta polita*.)
- Obolus apollinis* Eichwald, DAVIDSON (in part), 1853, British Fossil Brachiopoda, vol. 1, introduction, No. 3, figs. 51 and 52, p. 136, and Pl. IX, figs. 280-284 (not fig. 285, which represents *Obolus (Acritis) antiquissimus*). (No text reference. Figs. 280 and 281 appear to be drawn from the specimens figured by Kutorga, 1848, Pl. VII, figs. 10a and 10f, respectively; figs. 282, 283, and 284 are drawn from the specimens figured by Kutorga, 1848, Pl. VII, figs. 10b', 10c, and 10e, respectively.)

- Obolus apollinis* Eichwald, WESTERGÅRD, 1909, Medd. från Lunds Geol. Fältklubb, Ser. B, No. 4 (Aftryck ur K. Fysiografiska Sällskapets Handl., N. F., Bd. 20), p. 56, Pl. II, figs. 14-16. (Localities mentioned in Swedish. Figs. 14-16 are copied from Moberg and Segerberg, 1906, Pl. III, figs. 1-3, respectively.)

Obolus apollinis being the type of the genus, I have reproduced the diagnosis by Mickwitz [1896, p. 133] with the accompanying remarks:

The series of forms comprised under *O. apollinis*, and connected with each other by many transitions, show such departures in their extreme forms that an abundant material was necessary in order to show that they belong together. With the increasing number of different forms there was an increasing difficulty in grouping them and in deciding the question as to which of these many forms were to be regarded as species and which as varieties. The small oval valves corresponding to Eichwald's original in the Zoologia specialis show the generic characters much less pronounced than many of the forms described below. Still Eichwald's conception was retained and merely somewhat amplified by the incorporation of a small rounded form, because this form showed closer relation to Eichwald's original than to the more divergent large forms described as varieties.

Diagnosis: Shells flat, outline oval to rounded, tip of beak of the large valve somewhat drawn forward and somewhat curved inward. Concentric and radial striation faint and irregular, the latter somewhat unpronounced, at times lost in an irregularly rent shell surface, but always recognizable at the posterior edges of the shell. Front and side edges thin, sharp, brittle, lying in the same plane as the thickened edges of the beak. Area in the median line somewhat concave; pedicle furrow distinctly developed, slightly tapering toward the apex of the beak. Lines of folding of the area lamellæ slightly concave to the median line of the valve and converging into the apex of the beak. The thickening of the posterior half of the valve is massive; the slope of the thickening down to the middle of the valve, in the large valve, shows longitudinal striæ and transverse traces of the secondary vessels. The traces of the main vessels in both valves are broad and flat and on both sides marked at the bottom by narrow grooves. The grooves of the secondary vessels, radiating into the interior of the valves, are rectilinear, unbranched, and at right angles to the grooves of the main vessels. The central pit has the shape of the conventional heart, opens into the brachiocœle through the median furrow and shows longitudinal striæ at its posterior edge. The muscular attachments of the combined outside lateral and central muscles of the large valve are drawn out into furrows toward the beak, which extend beyond the posterior edge of the central pit.

Observations: The defective condition of the shells leaves many characters uncertain. Thus even in relatively well-preserved specimens the edges of the shells are broken off and show neither the anterior course of the main vessels nor the mouths of the secondary vessels where they enter the peripheral vascular canal.

The scars of the anterior lateral muscles of the small valve, which, owing to their position far forward, are also for the most part broken off with the edge of the valve, were seen in three specimens.

In the typical form there seems to be a certain correlation between form, shell surface, and internal configuration, but this correlation is not carried out very rigorously. The oval forms have the tip of the beak drawn somewhat farther forward; the radial striation in them is for the most part less pronounced, while the concentric striation is stronger and more roughly engraved. At the same time the shell surface is duller and lacks the strong varnish-like gloss which is peculiar to the *Oboli*. To this external condition corresponds a less thickening of the posterior part of the shell, and as a consequence a less pronounced development of all the characters connected with the thickening, such as septa, ridges, central pit, etc. The internal marks of the last-named specimens are all developed to a recognizable degree, but they lack relief.

Quite different is the case with the rounder forms. The shell surface is smoother and glossier, the concentric and radial striation more alike, though the latter is always fainter, and at times is overpowered by the beginnings of an irregular cracking of the surface, which is fully developed in *O. apollinis ingricus*. At the same time the internal configuration shows a plasticity often bordering on the monstrous.

* * * * *

To *O. apollinis* in the narrower sense belong most of the forms described by earlier authors, in particular *O. apollinis* Eichwald [1829, p. 274, Pl. IV, figs. 5a-b], *Ungula ovata* Pander [1830, p. 59, Pl. III, fig. 23] (while the valve figured by the same author in figs. 6a-b, Pl. XXVIII, belongs to a *Schmidtia*), *O. ingricus* von Leuchtenberg [1843, p. 16, Pl. II, figs. 7-8], *O. apollinis* de Verneuil [1845, p. 290, Pl. XIX, fig. 3c], *Aulonotreta polita* Kutorga [1848, p. 278, Pl. VII, figs. 10a, a', c?, d?, e?]; the other forms of Kutorga, so far as they may be recognized, belong to the varieties of Eichwald's species.

The specific name is derived from Apollo, the name *Obolus apollinis* signifying "a coin of Apollo."

FORMATION AND LOCALITY.^a—Upper Cambrian: (395f) *Obolus* conglomerate throughout the east Baltic region; (336c) *Obolus* sandstone at Reval; (395) *Obolus* sandstone at Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; (395b) *Obolus* sandstone at Ilgast; (9d) *Obolus* sandstone at Jaggowal, about 20 miles (32.2 km.) east-southeast of Reval; (336b) *Obolus* sandstone on Odensholm Island, about 55 miles (88.6 km.) west of Reval; (336m) *Obolus* sandstone at Baltischport, about 30 miles (48 km.) west of Reval; (336t) *Obolus* sandstone at Wiems, 5 miles (8 km.) north-northeast of Reval; and (336s) *Obolus* sandstone at Narwa; all in the Government of Esthonia, Russia.

(395z) *Obolus* sandstone at Jamburg on Louga (Luga) River; (336a) *Obolus* sandstone at Podolova (Putalova?) on Ijora (Ischora) River; (336u) *Obolus* sandstone on the bank of Louga (Luga) River, southwest of St. Petersburg; (336k) *Obolus* sandstone on Volkhof (Wolchow) River; (3361) *Obolus* sandstone on the bank of Sjass (Sias) River, near Lake Ladoga; all in the Government of St. Petersburg, Russia.

(336r) *Obolus* sandstone in the entire region between Volkhof (Wolchow) and Sjass (Sias) rivers on the east and Baltischport on the west, Governments of Novgorod, St. Petersburg, and Esthonia, Russia.

(311w) Drift boulder of *Obolus* sandstone [Wiman, 1902, p. 68], Mariehamn, Åland Island, Finland, Russia.

(386e) Drift boulder found near Lyck, East Prussia; and (386d) drift boulder found near Danzig, West Prussia; both in Germany.

(321, 321a-d, and 321o) Drift boulders of *Obolus* sandstone, Nos. 1-23, and 25-29 [Wiman, 1902, p. 68], on Fanton Island, parish of Börstil, Province of Stockholm; (3901) *Obolus* conglomerate at Klittberget, in Dalarne, Province of Kopparberg; (9e) Sandstone in the *Obolus* conglomerate at Boda, north of Rattvik, Dalarne; (311v [Wiman, 1902,

^a The collections of the United States National Museum contain specimens of *Obolus apollinis* from Localities 9d, 9e, 336s, 395, 395b, and 395z. The other localities mentioned are taken from the references given in the synonymy. The authority for each locality cited will be found in the list of localities, pp. 161-291.

p. 68]) Drift bowlder of *Obolus* sandstone, Erskolmen Island, parish of Börstil, southeast of Öregrund, Province of Stockholm; and (390m) conglomerate overlying the "glauconite sand" at Horn, Oeland Island; all in Sweden.

Middle Cambrian: (368) Quartzitic sandstone in the Pepper Mountains, near Sandomierz, on the Vistula, Russian Poland.

OBOLUS APOLLINIS INGRICUS (Eichwald).

Obolus ingricus EICHWALD, 1829, *Zoologia specialis*, vol. 1, p. 274. (Described in Latin as a new species.)

Obolus ingricus EICHWALD, 1843, *Beiträge zur Kenntniss des russischen Reiches*, Bd. 8, No. 2, pp. 140-141. (Characterized and discussed in German.)

Obolus apollinis Eichwald, DE VERNEUIL (in part), 1845, *Géologie de la Russie d'Europe*, by Murchison, de Verneuil, and de Keyserling, vol. 2, pt. 3, pp. 290-292 (not Pl. XIX, figs. 3a-d, which represent specimens of *Obolus apollinis*). (Described and discussed in French. The reference includes *Obolus (Acritis) antiquissimus*, *Obolus (Mickwitzella) siluricus*, *Obolus apollinis*, and *Obolus apollinis ingricus*, *Obolus apollinis* being figured.)

Obolus ingricus Eichwald, VON LEUCHTENBERG, 1843, *Beschreibung einiger neuen Thierreste der Urwelt von Zarskoe-Selo*, p. 16, Pl. II, figs. 7 and 8. (Not seen.)

Aulonotreta polita KUTORGA (in part), 1848, *Verhandl. Russ.-kais. min. Gesell. St. Petersburg für 1847*, pp. 279-282 (not Pl. VII, figs. 10a-f, which represent specimens of *Obolus apollinis*.) (Described and discussed in German as a new species. The text includes *Obolus apollinis ingricus*, *Obolus (Mickwitzella) siluricus*, and *Obolus apollinis*, the last species being figured.)

Obolus ingricus EICHWALD, 1860, *Lethæa rossica, ancienne période*, vol. 1, sec. 2, pp. 926-927. (Described and discussed in French.)

Obolus apollinis ingricus (Eichwald), MICKWITZ, 1896, *Mém. Acad. imp. sci. St.-Petersbourg*, 8th ser., vol. 4, No. 2, pp. 137-140, Pl. I, figs. 15-28. (Described and discussed in German.)

Mickwitz states that this shell has the same form as *O. apollinis* but that it is much larger and the surface is more frequently and strongly marked by the concentric striae and lines of growth; the central pit of the ventral valve is more pear-shaped. A full description is given of the details of exterior form and interior markings of the valves so far as known to him.

FORMATION AND LOCALITY.^a—**Upper Cambrian:** (336a) *Obolus* sandstone at Podolova (Putalova?) on Ijora (Ischora) River; and (395z) *Obolus* sandstone at Jamburg on Louga (*Luga*) River; both in the Government of St. Petersburg, Russia.

(395) *Obolus* sandstone at Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; (395a) *Obolus* sandstone at Tihala, near Jegelecht, 12 miles (19.3 km.) east of Reval; (336e) *Obolus* sandstone at Reval; (336t) *Obolus* sandstone at Wiems, 5 miles (8 km.) north-northeast of Reval; and (336s) *Obolus* sandstone at Narwa; all in the Government of Esthonia, Russia.

OBOLUS APOLLINIS MAXIMUS Mickwitz.

Plate VII, figure 9; Plate XIV, figures 7, 7a.

Obolus apollinis maximus MICKWITZ, 1896, *Mém. Acad. imp. sci. St.-Petersbourg*, 8th ser., vol. 4, No. 2, pp. 140-143, Pl. I, figs. 29-38. (Described and discussed in German as a new variety.)

Mickwitz states that this shell is very large, 21 mm. or more in diameter. It has more regular, radial, and concentric striations than the variety *ingricus* and the surface is smoother. The ventral valve near the beak is very thick. An elaborate description is given, accompanied by full illustration.

FORMATION AND LOCALITY.—**Upper Cambrian:** (395) *Obolus* sandstone at Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; and (395f [Mickwitz, 1896, p. 142]) *Obolus* conglomerate throughout the east Baltic region; both in the Government of Esthonia, Russia.

(336j) *Obolus* sandstone at Staroja Ladoga, Government of Novgorod, Russia.

OBOLUS APOLLINIS QUENSTEDTI (Mickwitz).

Text figures 34A-B, page 374.

Ungula convexa PANDER, 1830, *Beiträge zur Geognosie des russischen Reiches*, pp. 59 and 163, Pl. XXVIII, figs. 1a-b. (Characterized in German on p. 59; description of plate on p. 163.)

Ungula transversa PANDER (in part), 1830, *idem*, pp. 59 and 154, Pl. III, fig. 24 (not Pl. XXVIII, figs. 7a-b and (?) 8a-b, which represent specimens of *Obolus apollinis*). (Characterized in German on p. 59; description of plate on p. 154.)

^a All of the localities mentioned are taken from the references given in the synonymy. The authority for each locality cited will be found in the list of localities, pp. 161-291.

- Obolus apollinis* ZITTEL (in part) [not EICHWALD], 1880, Handbuch der Palæontologie, Bd. 1, Abth. 1, p. 664, fig. 488d (not figs. 488a-c, which represent *Obolus apollinis*). (No text reference. Fig. 488d is roughly copied from Quenstedt, 1837, Pl. III, fig. 7.)
- Obolus quenstedti* MICKWITZ, 1892, Mélanges géol. et paléontol. tirés du Bull. Acad. imp. sci. St.-Pétersbourg, vol. 1, p. 62, fig. 1, and footnote on p. 60. (The description of the species is incorporated with that of the genus, which is in German. The two specimens represented by fig. 1 were redrawn by Mickwitz, 1896, figs. 6A-B, pp. 79 and 117, and then copied in this monograph, figs. 34A and 34B, p. 374.)
- Obolus quenstedti* Mickwitz, HALL and CLARKE, 1892, Eleventh Ann. Rept. State Geologist New York for 1891, p. 243, figs. 244 and 245. (Generic reference questioned. Figs. 244 and 245 are copied from Mickwitz, 1892, fig. 1, p. 62.)
- Obolus quenstedti* Mickwitz, HALL and CLARKE, 1892, Forty-fifth Ann. Rept. New York State Museum for 1891, p. 559, figs. 244 and 245. (Text and figures copied from preceding reference.)
- Obolus quenstedti* Mickwitz, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 339, figs. 38 and 39. (Discusses species, questioning its reference to *Obolus*. Figs. 38 and 39 are copied from Mickwitz, 1892, fig. 1, p. 62.)
- Obolus apollinis quenstedti* MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 143-145, figs. 6A-B, p. 79, figs. 6A-B, p. 117, Pl. II, figs. 1-6. (Described and discussed in German; see below for translation of portions of the description. The text figures on p. 117, which are copied from those on p. 79, are copied in this monograph, figs. 34A and 34B, p. 374. Mickwitz's figures, pp. 79 and 117, are drawn from the specimens which he illustrated, 1892, fig. 1, p. 62, and which were copied by Hall and Clarke, 1892a, figs. 244 and 245, p. 243; 1892b, figs. 244 and 245, p. 559; and 1892c, figs. 38 and 39, p. 339.)
- Obolus quenstedti* Mickwitz, WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 385. (Translates part of the third paragraph on p. 25 of Mickwitz's paper, 1896, as below, and discusses the type species.)
- Obolus quenstedti* Mickwitz, MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, p. 120. (Compared, as the representative of *Obolus*, with "*Lingulella selwyni*," as the representative of *Lingulella*.)

Of this shell Mickwitz [1896, p. 25] says:

A more accurate study of the greatly increased material has convinced me that *O. quenstedti* can not be maintained as a species, since it is merely the terminal link of a series of variations, which, like var. *maximus* and *ingricus*, can be traced back to *O. apollinis*. Thus the typical species remains *O. apollinis* Eichwald.

In describing *O. apollinis quenstedti* Mickwitz [1896, p. 143] says:

This variety is distinguished externally from the forms thus far described of *O. apollinis* by the circular outline of its valves, their less pronounced arching (in the mean 0.159 for the large valve, and 0.183 for the small valve), and by its smoother and more shining external shell surface, while by its size it is allied to the varieties *ingricus* and *maximus* (in the mean 21.5 mm.). The radial striæ are more strongly developed and more uniformly distributed over the shell surface than in other forms of Eichwald's species, and they often exceed the concentric striæ in distinctness.

The shells show two extreme forms connected by intermediate links. Those forms also show a corresponding variation in the development of the internal characters. * * *

The internal shell surfaces of this variety (*quenstedti*) are most vigorously chiseled of all the forms of *O. apollinis*, and although in all the details of their internal configuration they show merely the typical form, yet by the peculiar development of the characters they present a picture differing from the other forms of Eichwald's species. The peculiarity in the development of the internal characters of this variety consists in this, that both the elevations and the depressions are strongly developed, and in this way double the relief of the pattern. At the same time details become apparent which in the other forms are distinguishable only by reflected light. Such is the longitudinal striation of the posterior edge of the central pit.

The varietal name was given in honor of F. A. von Quenstedt.

FORMATION AND LOCALITY.—Upper Cambrian: (395 [Mickwitz, 1896, p. 145]) *Obolus* sandstone at Joa; and (395a [Mickwitz, 1896, p. 144]) *Obolus* sandstone at Tihala; both near Jegelecht, 12 miles (19.3 km.) east of Reval, Government of Esthonia, Russia.

(395z [Mickwitz, 1896, p. 144]) *Obolus* sandstone at Jamburg, on Louga (Luga) River, Government of St. Petersburg, Russia.

OBOLUS? BAVARICUS (Barrande).

Plate XV, figures 10, 10a.

- Lingula bavarica* BARRANDE, 1868, Faune silurienne des environs de Hof, en Bavière, p. 100, fig. 62. (Described and discussed in French as a new species. Fig. 62 is copied in this monograph, Pl. XV, fig. 10.)
- Obolus? palliatus* BARRANDE (in part), 1868, idem, pp. 104-105, fig. 64 (not fig. 65, which represents the species *palliatus*). (Described and discussed in French as a new species. Fig. 64 is copied in this monograph, Pl. XV, fig. 10a.)
- Lingula bavarica* BARRANDE, 1868, Neues Jahrb. für Mineralogie für 1868, pp. 690-691, unnumbered plate, fig. 62. (Text and figure copied from Barrande, 1868a, p. 100, fig. 62.)
- Obolus? palliatus* BARRANDE (in part), 1868, idem, p. 693, unnumbered plate, fig. 64 (not fig. 65, which represents the species *palliatus*). (Text and figure copied from Barrande, 1868a, pp. 104-105, fig. 64.)

The author states [1868a, p. 100] that this shell can only be described by its external appearance, and that this does not enable him definitely to identify it with *Lingula* or one of the more recently distinguished genera *Lingulella* or *Obolella*. The shell is compressed. The only portion preserved near the beak is about 0.5 mm. thick. Its external surface is marked by somewhat irregularly spaced concentric striæ, which are reproduced on the internal cast. Traces of longitudinal striæ are shown on the fragment of shell preserved. The shell has a length of 17 mm. and its greatest width is 16 mm. Comparison is made with *Obolella plumbea* Salter, of the English rocks, and attention is called to the fact that the English species belongs to the group of the lower Llandeilo, constituting a transition between the primordial and second faunas like the schists of Hof.

FORMATION AND LOCALITY.—Passage beds between the Upper Cambrian and Ordovician: (303c [Barrande, 1868a, p. 100]) suburbs of Hof, Bavaria, Germany.

OBOLUS BELLI (Billings).

Plate XXXVIII, figures 3, 3a-b.

Lingula belli BILLINGS, 1859, Canadian Naturalist, 1st ser., vol. 4, pp. 431-432, figs. 7 and 8. (Described and discussed as a new species, as below. The specimens figured by Billings are redrawn in this monograph, Pl. XXXVIII, figs. 3 and 3a, but it is impossible further to identify Billings's figures with those in this monograph.)

Lingula belli BILLINGS, 1863, Geol. Survey Canada, Fifteenth Rept. Progress, figs. 47a-b, p. 124. (No text reference. Figs. 47a-b are copied from figs. 7 and 8, respectively, of the preceding reference.)

The original description by Billings follows:

Oval, apical angle about 75°, lateral margins somewhat straight or gently convex for two-thirds of the length, front angles and anterior margins broadly rounded; length one-fourth or one-third greater than the width; greatest width at about one-third the length or a little less from the front. Large specimens are one inch long and nine lines wide, but the usual size is one-third smaller.

The form so far as regards convexity of the valves is somewhat variable. In general the specimens are strongly convex, or very obtusely carinate from the beak to near the center of the shell, and have three flat slopes, one to each of the lateral margins and one to the front. The most prominent point is a little above the middle, and the anterior slope is always larger than the others. From this form, which is that of a very low three-sided pyramid, with all the angles and edges broadly rounded, there is a series becoming more and more convex, until all trace of the anterior slope is lost, while the two lateral slopes are only visible for a short distance below the beaks. By taking the extremes several species might be made out of this one, but I am satisfied that they would not in the end be sustained.

The surface is sometimes nearly smooth, but usually it is marked by concentric undulations of growth. I have not been able to detect any minute concentric striæ between the larger undulations, and on only one of all the specimens that I have seen are there any longitudinal striæ, and these are only faintly indicated on the cast of the interior. The specimens collected in the Chazy limestone in the neighborhood of Montreal are of a jet-black color and often exhibit a polished shining surface, but those in the same rock in the valley of the Ottawa above Carillon are light brown.

The species is closely allied to *L. antiqua* (Hall) but is not longitudinally striated. In the Potsdam sandstone on lots 21 and 22, in the 9th concession of the Township of Bastard, *L. antiqua* occurs in vast abundance, and among the specimens collected at that locality there are a great many which have almost exactly the same form as *L. belli*, the only difference being the longitudinal striæ.

I have also before me specimens from the Falls of St. Croix in Wisconsin, said to be *L. prima* of the Potsdam, and these also have the depressed pyramidal elevation, but are in outline suborbicular or obscurely subpentagonal. The elongated form sometimes referred to *L. antiqua* appears to me to be *L. acuminata* (Conrad), and differs from all the above by being convex from the beak all along the median line to the front.

Billings [1859, p. 432] has indicated the resemblance of this species to "*L. antiqua* Hall" = *Lingulella* (*Lingulepis*) *acuminata* (Conrad). In addition, I find traces of the heart-shaped cavity of the ventral valve (Pl. XXXVIII, fig. 3a) so characteristic of *Obolus* and its subgenera. So far as known to me this is the latest species of *Obolus* known to occur in any American geologic section.

The specific name was given in honor of Rev. A. Bell, of L'Original, near Montreal, Canada.

FORMATION AND LOCALITY.—Ordovician: Chazy formation at the following localities [Billings, 1859, p. 432]: (319n) *Island of Montreal*; (319o) near L'Original; and (319p) on Allumette Island; all in the St. Lawrence River valley, Canada.

(392h [Billings, 1859, p. 432]) Limestone of the Chazy formation in the valley of Ottawa River, above Carillon, Quebec, Canada.

OBOLUS CHINENSIS (Walcott).

Plate XXXIX, figures 7, 7a-b.

Obolus (Lingulella) chinensis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 328-329. (Described and discussed as below as a new species.)

General form broadly subovate, with the ventral valve broadly subacuminate and the dorsal valve oval, with the posterolateral slopes somewhat straightened. There is some variation in the proportions of width and length in different shells. Valves rather strongly convex for so thin a shell, in this respect resembling species of *Dicellomus*. Surface marked by fine concentric striæ and lines of growth and very fine undulating concentric lines; this outer surface is usually a dull black and adheres to the matrix; when the outer layer is exfoliated the surface is shiny black and marked by numerous radiating striæ in addition to concentric striæ; the inner surface shows a few scattered punctæ in addition to radiating and concentric striæ outside the visceral area. The shell is of medium thickness and formed of a thin outer layer and several inner layers or lamellæ that are slightly oblique to the outer layer; the lamellæ are more numerous and more oblique to the outer layer over the anterior and anterolateral portions of the shell. The ventral valves average 3 mm. in length, with width varying from 2 mm. to 2.5 mm. The dorsal valve is slightly shorter than the ventral when the two valves have the same width.

The interior of the ventral valve shows that the area is short and divided midway by a narrow pedicle furrow that merges into the visceral area which extends forward about one-third the length of the valve; on each side of the anterior central portion of the visceral area there are two small trapezoidal areas within which the central scars and the middle and outside lateral muscle scars were attached; the small transmedian and anterolateral muscle scars are situated close to the main vascular sinus opposite the anterior portion of the central visceral area. A partial cast of the interior of the dorsal valve shows a rather wide visceral area with the anterolateral scars about the center of the valve and the central scars about one-fourth of the distance back from the center to the posterior margin. Of the impressions left by the vascular system only the main vascular sinuses of the ventral valve have been seen. These are situated about midway between the central visceral area and the margins of the valve.

Observations.—This species occurs abundantly in association with *Aerotreta shantungensis* Walcott. It is closely related in form to *Obolus prindlei* (Walcott) of the upper *Olenellus* zone of eastern New York, and belongs with a group of small shells that have a wide vertical and geographic range, as is noted under the description of *O. prindlei*. With the data available for comparison it differs from *O. prindlei* in its shorter cardinal area, and visceral area in the dorsal valve. From *Lingulella damesi* (Walcott) it differs in being broader in proportion to its length.

FORMATION AND LOCALITY.—Middle Cambrian: (C62) Earthy layer in the middle limestone of the Kiulung group [Blackwelder, 1907a, pp. 37 and 40 (last list of fossils) and fig. 10 (base of bed 7), p. 38], 2.5 miles (4 km.) south of Yenchuang, on the north-northeast spur of Hulusan, Sintai district, Shantung, China.

OBOLUS COMPLEXUS Barrande.

Plate XII, figures 3, 3a, 8, 8a.

Obolus? complexus BARRANDE, 1879, Système silurien du centre de la Bohême, vol. 5, pt. 1, Pl. XCV, figs. iii: 1-2; Pl. CXI, figs. vi: 1-2; Pl. CXIII, fig. v; and Pl. CLII, fig. ii: 4. (No text reference. Pl. XII, figs. 3, 3a, 8, and 8a, of this monograph are copied from Pl. CLII, fig. ii: 4A; Pl. CXIII, fig. v: A; Pl. XCV, figs. iii: 1A-B; and Pl. XCV, fig. iii: 2C, respectively.)

Obolella?? complexus Barrande, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 73, fig. 31. (Merely suggests change in generic reference. Fig. 31 is copied from Barrande, 1879b, Pl. CLII, fig. ii: 4A.)

Schmidtia?? complexus Barrande, MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 19-20. (Generic relations discussed in German.)

Barrande [1879b] recognized the relations of this species to *Obolus*, although at the time he did not have the results of Mickwitz's studies to aid him. The latter [1896, p. 19] considers

that Barrande's figure [1879, Pl. CLII, fig. II: 4] shows in the arrangement of the internal characters a remarkable similarity to the large valve of *Schmidtia*. (This figure is represented in Pl. XII, fig. 3, of this memoir.) A comparison with *O. feistmanteli* (Barrande) (Pl. XII, fig. 1d) shows the relation of the interior markings in the two species. However, the figure of *O. complexus*, which is an internal cast, has a pointed projection that indicates the presence of the transmedian and anterior lateral muscle scars much closer to the margin of the shell than the other species of the genus. I think, however, that we are justified in referring the species provisionally to *Obolus*. The specimens figured by Barrande [1879b, Pl. XCV, figs. II: 1-2] do not appear to me to represent this species. The valve from Kruschna Hora (Pl. XII, fig. 3a) probably represents a dorsal valve. All the characters known to me are shown by the figures. Hall and Clarke [1892c, p. 73] considered that the species might be a genuine *Obolella*.

FORMATION AND LOCALITY.—Lower Ordovician: (303i) *Étage d1*, *Kruschna Hora*; (303h) *Étage d1*, at Milinsky Wrch, near Woleschna; and (303g) *Étage d1*, at Rabenberg; all [Barrande, 1879b, Pls. XCV and CXI] in Bohemia, Austria-Hungary.

OBOLUS CYANE (Billings).

Plate XXVII, figures 4, 4a-b.

Lingula cyane BILLINGS, 1865, Geol. Survey Canada, Paleozoic Fossils, vol. 1, p. 216, figs. 200a-d, p. 215. (Described. Billings's type specimens are redrawn in this monograph, Pl. XXVII, figs. 4, 4a-b, but it is impossible further to identify his figures with those in this monograph.)

Glossina cyane (Billings), SCHUCHERT, 1897, Bull. U. S. Geol. Survey No. 87, p. 224. (Merely changes generic reference.)

General form ovate cuneate, broadly rounded at the front and sides, with the ventral valve subacuminate and the dorsal valve broadly rounded at the beak; valves rather strongly convex, especially the dorsal. Surface marked by concentric striæ and slight undulations of growth and by very fine radiating striæ; when the outer surface is exfoliated the inner layers or lamellæ are marked by numerous radiating striæ and concentric lines and undulations of growth; the casts of the interior show essentially the same markings as the inner layers, except over the visceral area, which is largely covered with fine papillæ corresponding to the minutely pitted surface of the shell's interior. The shell is thick and built up of a thin outer layer and numerous inner layers or lamellæ arranged over the anterior portions of the shell obliquely to the outer surface. Three ventral valves have an average length of 7 mm., with a width of 6 mm.; a dorsal valve 6 mm. in length is the same in width. The area of the ventral valve, as shown in a cast, is divided at the center by a strong pedicle furrow and about halfway between the pedicle furrow and the lateral margin by a sharp flexure line. The striæ of growth cross the area parallel with its base and show very clearly on the cast of the pedicle furrow. The area forms a thin shelf between the pedicle groove and the lateral margins, the undercut extending well back under the area. The area of the dorsal valve is relatively short and narrow, scarcely showing when viewed from above.

The cast of the visceral cavity is strongly marked, but in none of the specimens are the muscle scars shown. The central groove is shown in the cast by a rounded ridge, and the path of advance of the trapezoidal area (c), in which the central, middle, and outside lateral muscle scars occur, is beautifully shown by Plate XXXII, figure 4, the transverse ridges representing the lines of growth. The main vascular sinuses are fairly well shown in the same figure. There are no traces of a median septum in the ventral valve, but this structure is clearly shown in the casts of the dorsal valve, extending forward between the anterior lateral muscle scars.

The cast of the interior of the dorsal valve shows that in the adult the shell was thickened over the visceral area and that the muscle scars were located on a comparatively elevated platform. The position and form of the anterior lateral and central muscle scars and the direction of the scar of the parietal band are fairly well shown by Plate XXVII, figure 4b, as is also the umbonal scar (g).

Observations.—This is a most interesting species on account of its preserving well into Ordovician time the characteristics of well-marked forms of *Lingulella* from the Middle and Upper

Cambrian. This may be seen by comparing with figures of *Lingulella hayesi* (Walcott) (Pl. XXV) of the Middle Cambrian and *Lingulella radula* Matthew (Pl. XLV) of the Upper Cambrian.

Obolus cyane is of the same type as *Lingulella iole* (Billings) and is associated with it in a horizon that appears to correspond with the upper portion of the Chazy and base of the Trenton of the New York section. It differs in being more cuneate and less elongate.

FORMATION AND LOCALITY.—Lower Ordovician: (314d) Limestone of Division P [Billings, 1865a, p. 216] of the "Quebec group," 4 miles (6.4 km.) northeast of Portland Creek, Newfoundland.

OBOLUS DISCOIDEUS (Hall and Whitfield).

Plate XVIII, figures 6, 6a-d.

Obolella discoidea HALL and WHITFIELD, 1877, U. S. Geol. Expl. 40th Par., vol. 4, p. 205, Pl. I, figs. 1 and 2. (Described.

One of Hall and Whitfield's specimens, likely the one represented by fig. 2, is redrawn in this monograph, Pl. XVIII, fig. 6c; the specimen represented by fig. 1 is not figured in this monograph.)

Obolella discoidea Hall and Whitfield, WALCOTT, 1884, Mon. U. S. Geol. Survey, vol. 8, p. 14. (New localities mentioned.)

Obolella? discoidea Hall and Whitfield, WALCOTT, 1886, Bull. U. S. Geol. Survey No. 30, p. 111. (Questions generic reference.)

Obolella? discoidea Hall and Whitfield, HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 69. (Questions generic reference.)

Obolus (Lingulella) discoideus (Hall and Whitfield), WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 673. (Merely changes generic reference.)

General form broad ovate to subcircular, with the ventral valve obtusely acuminate and the dorsal valve more broadly rounded posteriorly; both valves depressed convex, the umbo of the ventral valve rising slightly toward the posterior margin. Surface of shell marked by very fine, concentric undulating striæ and lines of growth. When partly exfoliated the inner lamellose layers are imbricated, their outer edges being irregular. The only traces of the interiors observed show fine concentric striæ of growth. Shell of medium thickness. It is built up of a very thin outer layer and numerous inner layers arranged more or less obliquely to the outer layer over the frontal portions. The largest valve has a length of 4.25 mm. with a width of 4 mm. No interiors of either valve have been found among a large number of specimens.

Observations.—This pretty little shell is certainly not an *Obolella*. In shell structure and form it is like *Obolus*.

FORMATION AND LOCALITY.—Lower Ordovician: (185z) Limestones at the base of the Lower Ordovician [Walcott, 1908f, p. 191], in Blacksmith Fork Canyon, about 9 miles (14.4 km.) east of Hyrum, Cache County, Utah.

Upper Cambrian: (313j [Hall and Whitfield, 1877, p. 205]) Limestone in the Eureka district; (66) Dunderberg shale [Walcott, 1908f, p. 184], on the first ridge north of the Dunderberg mine; (62) limestone in the Dunderberg shale [see Walcott, 1908f, p. 184], in canyon immediately north of Adams Hill; and (64) limestone near the Bullwhacker mine; all in the Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

(8f) Limestones at summit of canyon, 10 miles (16.1 km.) south of Egan Canyon, east side of Egan Range, White Pine County, Nevada.

(54e) About 200 feet (61 m.) above the Middle Cambrian and 1,025 feet (212.4 m.) below the top of the Upper Cambrian, in limestones forming 3 of the St. Charles formation; and (54f) about 150 feet (45.7 m.) above the Middle Cambrian and 1,075 feet (327.7 m.) below the top of the Upper Cambrian in the light-gray sandstone forming 4 of the St. Charles formation; both in Blacksmith Fork Canyon [Walcott, 1908f, p. 193], about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

(56g) Limestone of the St. Charles formation [Walcott, 1908a, p. 6], in the valley of the stream which flows into Mill Canyon from the west, about 6 miles (9.6 km.) west-southwest of Liberty, and 15 miles (24.2 km.) west of Montpelier, Bear Lake County, Idaho.

(151) Limestone in point overlooking Churn Canyon, on the west side of the Bridger Range, Gallatin County, Montana.

Middle Cambrian: (58) Shaly limestone in upper beds of Secret Canyon shale, east side of New York and Secret canyons, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

Specimens that are somewhat doubtfully referred to this species occur at the following locality:

Upper Cambrian: (302r) About 1,000 feet (305 m.) above the quartzitic sandstones in the "Yogo limestone (Devono-Silurian)" of W. H. Emmons [1907, p. 34], near Princeton, Philipsburg quadrangle (U. S. Geol. Survey), Granite County, Montana.

OBOLUS DOLATUS (Sardeson).

Text figures 35A-C.

Lingula dolata SARDESON, 1896, Bull. Minnesota Acad. Nat. Sci., vol. 4, p. 95, Pl. VI, fig. 12. (Described as a new species.)

Only the exterior of the valves of this species is known. The outline of the valves is much like that of *Obolus matinalis* (Hall) (Pl. VIII), and it does not differ more in this respect from

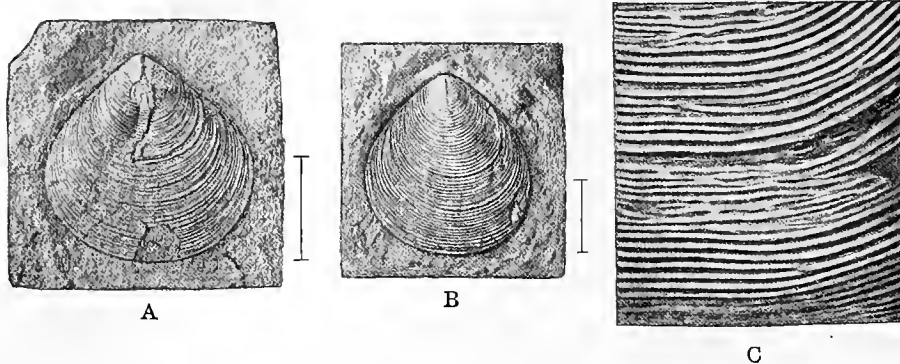

FIGURE 35.—*Obolus dolatus* (Sardeson). A, Exterior of a large, crushed ventral valve, the type specimen. B, Exterior of an elongate dorsal valve. C, Surface ridges on the front part of another dorsal valve, $\times 14$.

The specimens represented are all from Locality 339, near Stillwater, Minnesota, in beds which are reported by Sardeson to be the Lower Ordovician Oneota dolomite.

that species than specimens of *O. matinalis* differ from each other. The chief specific distinction is in the fine, narrow, sharp, slightly undulating, slightly inosculating concentric ridges; the spaces between the ridges are about twice the width of the ridges. This surface is somewhat similar to that on the interspaces between the beaded ridge of *Obolus* (*Mickwitzella*) *siluricus* (Pl. XV, fig. 1c).

It may be that when specimens of the interior of the valves are found other differences from *O. matinalis* will be noted. *Obolus dolatus* appears to be a Lower Ordovician representative of the widely distributed *O. matinalis*.

FORMATION AND LOCALITY.—Lower Ordovician: (339 [Sardeson, 1896, pp. 95 and 96]) from beds referred by Sardeson to the Oneota dolomite, Stillwater, Washington County, Minnesota.

OBOLUS EICHWALDI Mickwitz.

Obolus eichwaldi MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 154-155, Pl. II, figs. 15a-d. (Described and discussed in German as a new species.)

Of this species Mickwitz had only the posterior portion of a dorsal valve and some small fragments. He states that the essential characteristics which distinguish it from *O. triangularis* Mickwitz are the much finer, more regular, concentric striation and the somewhat irregular, undulating, radial ribs, which give the surface a somewhat wavy appearance through their varying strength and occasional interruption. Mickwitz speaks of the circular form of the shell, but the lines of growth on the fragment illustrated (Pl. II, fig. 15a) indicate a somewhat transverse shell. He also mentions peculiarities in the area of the dorsal valve. The student is referred to the elaborate description of Mickwitz for further details.

Mickwitz states that *O. eichwaldi* is one of the rarest species of the *Obolus* sandstone.

The specific name was given in honor of C. E. von Eichwald.

FORMATION AND LOCALITY.—Upper Cambrian: (395 [Mickwitz, 1896, p. 155]) *Obolus* sandstone at Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval, Government of Esthonia, Russia.

OBOLUS ELEGANS Mickwitz.

Plate XV, figure 3.

Obolus elegans MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 157-158, Pl. II, fig. 18. (Described and discussed in German as a new species.)

Only fragments were found of "this most delicate species of the *Obolus* sandstone." The shell appears to have been roundish and rather strongly convex, judging from one of the larger fragments, which does not exceed 5 mm. in diameter.

The species is distinguished from all others of the *Obolus* sandstone by the rounded, narrow, radiating ribs, which are increased by frequent interpolation from the umbo toward the front margin. The surface is also marked by fine concentric striation. Nothing is known of the internal characters.

Mickwitz states that this is one of the rarest of the known species of the *Obolus* sandstone.

In some collections made by Schmalensee I found nearly an entire specimen of the exterior of the ventral valve; this is illustrated by Plate XV, figure 3. The surface of this shell is much like that of *Botsfordia cælata* (Hall) (Pl. LIX, fig. 1b).

FORMATION AND LOCALITY.—Upper Cambrian: (395 [Mickwitz, 1896, p. 158]) *Obolus* sandstone at Joa, near Jegerlecht, 12 miles (19.3 km.) east of Reval; and (395b) *Obolus* sandstone at Ilgast; both in the Government of Esthonia, Russia.

OBOLUS FEISTMANTELI (Barrande).

Plate XII, figures 1, 1a-f, 9, 9a.

Lingula feistmanteli BARRANDE, 1879, *Système silurien du centre de la Bohême*, vol. 5, Pl. CVI, figs. iv: 1-14; Pl. CX, figs. viii: 1-4. (No text reference. Pl. XII, figs. 1, 1a, 1d, and 1f of this monograph are copied from Barrande's figures, Pl. CXVI, figs. iv: 7a, 11a, 4a, and 12f, respectively.)

General form rounded ovate to rounded subtriangular; ventral valve subacuminate, with the dorsal valve rounded subacuminate; valves moderately and almost uniformly convex. Surface of the shell marked by concentric undulations and striæ of growth and, apparently, fine radiating striæ. The latter are shown only on one specimen, as the outer surface usually adheres to the sandstone matrix, as in Plate XII, figure 1a. When the outer surface of the shell is exfoliated, the surface of the inner layers is marked by numerous fine radiating striæ (Pl. XII, figs. 1 and 1f), with more or less obscured concentric lines of growth. The radiating striæ appear to be distributed over the entire surface of the inner lamellæ of the shell, but are strongest on the inner, oblique layers of the anterior portion. In some instances the striæ on the oblique lamellæ are somewhat irregular (Pl. XII, fig. 1e); the inner surface of the shell is marked by small pits or punctæ and by obscure concentric lines of growth. The punctæ are distributed irregularly, being most prominent in the visceral portion. The general character is well shown in Plate XII, figure 1f. The shell is formed of a thin outer layer, with numerous inner layers or lamellæ over the anterior and outer portions. These inner lamellæ over the anterior portion of the shell are oblique to the outer layer, and when the shell is partly exfoliated they appear as imbricating layers (Pl. XII, figs. 1 and 1f). The layers or lamellæ formed in the central and posterior portions of the shell are relatively strong, and give considerable thickness to the shell. When these are exfoliated and the oblique anterior lamellæ are preserved, a shallow but well-defined depressed rim extends all around the valves. This rim shows more or less distinctly in the cast of the interior of the shell (Pl. XII, figs. 1b and 1e). This species varies somewhat in size and outline of the valves, but the variation shown is very slight in a large series of specimens from the typical locality. A ventral valve 16 mm. in length has a width of 15 mm. A dorsal valve, represented in figure 1e, is slightly wider than long. Usually the length and width of the dorsal valves is the same.

Casts of the interior of the ventral valve show a very clearly defined area. This is rather short for so large a shell (Pl. XII, fig. 1b); it is divided midway by the cast of a narrow, rather deep, pedicle groove; flexure lines have not been observed. The area extends well forward on the cardinal slopes and is marked by strong striæ of growth parallel to its front margin. One of the casts indicates that the area formed a narrow shelf between the pedicle groove and the lateral margins. The area of the dorsal valve is short and extends but a short distance out on the cardinal slopes.

Casts of the visceral cavity are well shown for both valves (Pl. XII, figs. 1b and 1e). It resembles that of *Obolus matinalis* (Hall) and *O. apollinis* Eichwald. The median septum has not been seen in either valve. A narrow furrow extends down the center of the dorsal valve between the central scars. A similar median depression is seen in the posterior portion of the visceral cavity of the ventral valve.

The muscle scars of the ventral valve are not clearly defined. The umbonal scar is indicated in one specimen (Pl. XII, fig. 1b). It is divided, but no trace of a pedicle scar has been

seen between the two. In the dorsal valve the umbonal scar is very close to the area and extends some distance on each side of the median line. It is marked by fine striæ subparallel to the longitudinal axis of the shell. In one cast (Pl. XII, fig. 1b) the position of the transmedian and anterior lateral scars is indicated; also the area in which the central, middle, and outside lateral scars occur, but the scars are not differentiated. In the dorsal valve (Pl. XII, fig. 1e) the central (h) and anterior lateral (j) scars are clearly defined also the position of the transmedians (i).

Portions of the markings left on the shell by the vascular system are well preserved in a few specimens. The description is of the cast, or as the markings are shown on the thin inner layer. The main sinuses are slightly rounded ridges that arch from the beak outward toward the center and then inward well toward the anterior margin. Those of the ventral valve are shown in Plate XII, figures 1b, 1c, and 1d, and the dorsal in figure 1e. The interior lateral branches in the ventral valve extend transversely from the main sinus nearly to the median line, except toward the front, where they arch slightly backward (Pl. XII, fig. 1c); the exterior lateral branches arch forward to the edge of the depressed rim, where they appear to pass into the small interosculating canals that cross the rim to the outer margin, each canal dividing into three or more branches; the peripheral vascular canal of Mickwitz [1896, p. 97] does not appear on any of the specimens available for study, but this may be owing to our not having the inner surface of the inner layer to examine.

The parietal scar is distinctly shown in front of the visceral cavity in both valves, but it has not been traced outside of the main sinus, although the positions of the transmedian and anterior lateral scars in the dorsal valve (Pl. XII, fig. 1b) indicate its approximate lateral extension.

Observations.—This large fine species is extensively illustrated by Barrande, but the material at his command evidently did not satisfactorily show the muscle scars and vascular markings of the interior of the valves. One figure of the ventral valve [1879b, pl. CVI, fig. iv: 4] indicates the relative position of the main vascular canals and muscle scars (copied on Pl. XII, fig. 1d, of this monograph), but it was not sufficiently clear to convince Mickwitz [1896, pp. 19–20] that the species should be referred to *Obolus*, and Hall and Clarke [1892c, pp. 68–69] suggested that it might be an *Obolella*. I found in the collections of the Museum of Comparative Zoology at Cambridge a number of specimens showing casts of the interior of both valves. Of these, three are figured in this monograph (Pl. XII, figs. 1b, 1c, 1e, 9, and 9a). Plate XII, figure 1c, is of a specimen preserving the thin inner layer, on the exterior of which vascular markings are beautifully preserved. Owing to the coarse character of the sandstone matrix, the interior casts preserve only traces of the main sinuses. Figure 1e represents a similar specimen in which the exterior lateral branches of the main sinus appear to subdivide at the inner edge of the flattened rim and to continue across the rim to the outer edge, inosculating and bifurcating in an irregular manner.

This is one of the most recent as well as the largest species of the genus. In form and the arrangement of the vascular markings and muscle scars it may be compared with *O. matinalis* (Hall), which, however, is a much smaller species from the Middle Cambrian fauna. In outline, size, and general arrangement of the muscle scars and visceral cavity the species may be compared with *Obolus (Lingulobolus) affinis* (Billings) (Pl. XVI, figs. 1, 1a–e).

The specific name was given in honor of K. Feistmantel.

FORMATION AND LOCALITY.—Lower Ordovician: (303i [Barrande, 1879b, Pl. CX]) Sandstone of *Étage d1*, at *Kruschna Hora*; and (303j [Barrande, 1879b, Pl. CVI]) *Étage d1*, at *Czerhowitz*; both in Bohemia, Austria-Hungary.

OBOLUS FRAGILIS (Walcott).

Plate XXIII, figures 5, 5a–e.

Obolus (Lingulella) fragilis WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 404. (Described and discussed essentially as below as a new species.)

General form ovate, with the ventral valve subacuminate and dorsal valve broad ovate; valves apparently moderately convex, as determined from the specimens more or less compressed in the shale. Surface of shell marked by concentric lines of growth, and what appears

to be an exceedingly fine papillose surface, which is apparently produced by the inosculation of irregular, raised striæ, as on the surface of *Obolus (Westonia) ella* (Hall and Whitfield) and *Lingulella ferruginea* Salter and on a larger scale by *Lingulella radula* Matthew. When the outer layer of the shell is exfoliated, very fine concentric and radiating striæ occur on the surface of the inner layers. The shell is thin and formed of an outer layer and one or more thin layers or lamellæ.

The average length of the ventral valve is about 5 mm.; width, 4 mm. The dorsal valve is a little shorter.

The rather long area of the ventral valve is divided midway by a strong pedicle groove (Pl. XXIII, fig. 5). The area of the dorsal valve is clearly defined on casts of the interior; it is about three-fifths the width of the valve and is arched forward at the center.

The casts of the interior of the valves show traces of the vascular markings, but nothing very definite can be said of them.

Observations.—This pretty little species is closely related to *Lingulella ferruginea* Salter, with which it is associated in the shales of Manuels Brook. It is distinguished from the latter by its broad form and thinner shell.

FORMATION AND LOCALITY.—**Middle Cambrian:** (1a) Shales near the top of No. 6 of the Manuels Brook section; (1) shales of zone A of No. 7 of the Manuels Brook section; and (2) shales of zone B of No. 7 of the Manuels Brook section; all on Manuels Brook (see Walcott, 1891b, p. 261, for position in section), Conception Bay, Newfoundland.

OBOLUS? INFLATUS Westergård.

Obolus ? inflatus WESTERGÅRD, 1909, Medd. från Lunds Geol. Fältklubb, Ser. B, No. 4 (Aftryck ur K. Fysiografiska Sällskapet's Handl., N. F., Bd. 20), p. 76, Pl. V, fig. 25. (Described in Swedish as a new species; see below for translation.)

The original description by Westergård follows:

Interior of shell unknown, hence the generic identification is uncertain. The outer contour is almost elliptical, being somewhat less broad than high. The thin shiny shell is posteriorly sharply convex and slopes from there to the anterior margin. It has somewhat uneven, fine, but very distinct concentric striæ and indistinct radial striæ. Even where the shell is exfoliated the radial striation is apparent.

FORMATION AND LOCALITY.—**Passage beds** between the Upper Cambrian and the Ordovician: (310x [Westergård, 1909, p. 76]) The uppermost limestone stratum, in beds equivalent to the *Cerato pyge* limestone, at Jerrestad, Province of Malmöhus, Sweden.

OBOLUS ISMENE Walcott.

Plate XI, figures 3, 3a-b.

Obolus ismene WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 325. (Characterized as below as a new species.)

This species is characterized by its elevated umbo, flattened posterior lateral margins, and relatively thin shell.

All that is known of the exterior surface indicates that it was nearly smooth, marked only by fine concentric striæ of growth. The inner layers of the shell are beautifully marked by fine concentric and radiating striæ that give the surface a cancellated appearance. The shell is built up of several layers or lamellæ that become more oblique to the outer surface toward the front.

FORMATION AND LOCALITY.—**Upper Cambrian:** (369) Sandstone in the Elvins formation, in the eastern limits of the town of Flat River, St. Francois County, Missouri.

OBOLUS LAMBORNI (Meek).

Plate XXII, figures 2, 2a-n.

Lingulella ? lamborni MEEK, 1871, Proc. Acad. Nat. Sci. Philadelphia for 1871, vol. 23, pp. 185-187, fig. 1. (Described and discussed as a new species.)

Lingulella lamborni MEEK, KEYES, 1894, Missouri Geol. Survey, vol. 5, pt. 2, pp. 38-39, Pl. XXXV, figs. 5a-d. (Described.)

General form broadly ovate, with the ventral valve obtusely acuminate and the dorsal valve rather broadly oval; convexity apparently moderate, judging from specimens of the

shells as they occur flattened out in the argillaceous shales. Surface of the shell marked by concentric lines and striæ of growth, and fine, slightly undulating striæ in the interspaces, and fine radiating striæ; the interior surface of the shell was strongly pitted or punctate, especially in the posterior half (Pl. XXII, figs. 2, 2a, 2i, and 2j). The shell was relatively thin, and formed of a thin outer layer and one or more inner layers or lamellæ.

One of the larger ventral valves from Missouri has a length of 8.5 mm.; width, 7.5 mm., as it occurs flattened in the shale; an associated dorsal valve has a length and width of 8 mm. The average size of the specimens from Tennessee is about 7 mm. for the ventral valve; a few shells from Georgia are unusually large; one dorsal valve (Pl. XXII, fig. 2i) has a length of 15 mm., width 12 mm.; in the flattened shell.

As shown in the cast the area of the ventral valve is rather long, and is divided midway by a strong pedicle furrow and marked midway between the furrow and the cardinal margins by a narrow flexure line. The striæ of growth cross the area parallel with its base and extend over the cast of the pedicle furrow; they are very fine and closely grouped together on the flexure line and on the lateral slopes. The area of the dorsal valve is rather long and extended well out onto the cardinal slopes; it is marked in several specimens by unusually strong flexure lines: the striæ of growth cross it parallel to its base, curving sharply forward at the median line. From the condition of the casts of the cardinal area it is evident that it formed in both valves a thin shelf, the undercut extending backward far under the area much as in *Lingulella ampla* (Owen) (Pl. XXVIII), *Lingulella acutangula* (Roemer) (Pl. XVII), etc.

Casts of the interior of the ventral valve (Pl. XXII, fig. 2b) show in the visceral cavity (v) traces of the heart-shaped pit (x). There are no traces of a median septum in the ventral valve, but it is shown in the casts of a dorsal valve as a very narrow, clearly defined short depression, extending from a point in front of the anterior lateral muscle scars back between the central muscle scars (Pl. XXII, fig. 2g).

Only the anterior lateral muscle scars are distinctly shown in the ventral valve. In one specimen from Tennessee the trapezoidal area (c) is well preserved, but the central scars and middle and outside laterals can not be differentiated (Pl. XXII, fig. 2f).

In the dorsal valve the central muscle scars (h), the anterior laterals (j), and the trans-medians (i) are all discernible. The anterior laterals are small and situated near the center of the shell, the centrals occurring some distance back and near the median septum, somewhat as in *Lingulella ampla* (Owen) (Pl. XXVIII). Portions of the markings left on the interior of the shell by the vascular system are shown on a cast of the interior. The main or trunk sinuses are best shown in the ventral valve in specimens represented in Plate XXII, figures 2, 2a, 2b, and for the dorsal valve in figure 2i. The parietal scar (ps) is distinctly shown in front of the visceral area of the ventral valve (Pl. XXII, figs. 2 and 2b) and the dorsal valve (figs. 2g and 2h); in both valves it extends out to the main sinuses (Pl. XXII, figs. 2 and 2h), but it is not observed beyond them.

Observations.—This fine species is well characterized by the strongly pitted inner surface and the elongate visceral area of the dorsal valve. The specimens from the type locality at Mine Lamotte are usually more or less broken and crushed, but a few in the United States National Museum show the form and outline and, more rarely, traces of the interior visceral and muscle scar markings. The material from Tennessee is much more abundant and somewhat better preserved; a marked variation is shown in the size and number of the interior pits or punctæ, and a considerable range in the outline of the valves; the latter is mainly to be attributed to distortion as the result of compression and a slight movement in the shale. Most of the specimens from Tennessee are about the same size as those from Missouri, but a number of larger shells were found about 50 feet lower in the section which are nearly double the average size of the specimens from Missouri and Tennessee. I am not able to discover any other differences that lead to considering them as a distinct species. The specimens are flattened in the shale, which gives rise to more or less distortion. The most nearly related species is *Obolus willisi* (Walcott) (Pl. XXIII) of the Middle Cambrian of Tennessee. The latter differs in being shorter in proportion to its width, in the nearly transverse, obtuse posterior

margin of the dorsal valve, and in the position of the central muscle scars. Specimens from the limestone just above the shales at Mine Lamotte are moderately convex and more elongate than those compressed in the shale. Some shells suggest the outline of *Lingulella acutangula* (Pl. XVII).

FORMATION AND LOCALITY.—**Upper Cambrian:** (7d) Shales in second cliff 0.125 mile (0.2 km.) west of Peak, 3 miles (4.8 km.) south of Clinton, Briceville quadrangle (U. S. Geol. Survey), Anderson County; and (122a) shale at the headwaters of Forgey Creek, northwestern part of the Greeneville quadrangle (U. S. Geol. Survey), Hawkins County; both in Tennessee.

Middle Cambrian: (11j)^a Shale and limestone in the basal part of the Bonnetterre limestone, Mine Lamotte, Madison County; (369f) limestone at Fredericktown, Madison County; (11m) drill cores of limestone at horizons 10 and 20 feet (3 and 6 m.) above the Lamotte sandstone, St. Francois County; and (369h) shale at Mine Lamotte, Madison County; all in Missouri.

(331) Rogersville shale 1 mile (1.6 km.) south of Fletcher, Greene County, Virginia.

(102) Rogersville shale just south of road, one-half mile (0.8 km.) southwest of Rogersville on the road to Melinda Ferry [Keith, 1896a, areal geology sheet]; (103) second shale south of the ridge of sandstone in the Rome formation ("Town Knobs"), on the road from Rogersville to Dodson Ford, near the line between the Morristown and Greeneville quadrangles (U. S. Geol. Survey); (121) Rogersville shale, road just east of Harlan Knob, 4 miles (6.4 km.) northeast of Rogersville [Keith, 1905, areal geology sheet]; (101b) Rogersville shale, just east of the schoolhouse, 3.5 miles (5.6 km.) southwest of Rogersville on the road to Melinda Ferry [Keith, 1896a, areal geology sheet]; and (124a) shales (Nolichucky?) overlying the limestone which rests on the Rogersville shale, on Big Creek, southeast of Harlan Knob, 4 miles (6.4 km.) northeast of Rogersville [Keith, 1905, p. 4, and areal geology sheet]; all in Hawkins County, Tennessee.

(140a) Shales 200 yards (182.9 m.) east of Thomas Mills, 5 miles (8 km.) north of Cave Spring [Hayes, 1902, historical geology sheet], Floyd County, Georgia.

OBOLUS LAMBORNI MINIMUS (Walcott).

Pl.

Plate XXV, figures 4, 4a-b.

Obolus (Lingulella) lamborni minimus WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 407. (Discussed as below as a new variety.)

This variety in its ventral valve closely resembles the adult form of the ventral valve of *Obolus lamborni* (Meek). The dorsal valve also has the same general form as most of the dorsal valves of the species. In comparing, however, the young specimens of the same size with the variety *minimus* the ventral valves appear to be more obtuse in the young of *O. lamborni*.

FORMATION AND LOCALITY.—**Middle Cambrian:** (101 and 101a)^b Rogersville shale, just above the road in the hill west of the schoolhouse, 3.5 miles (5.6 km.) southwest of Rogersville on the road to Melinda Ferry [Keith, 1896a, areal geology sheet], Hawkins County; (103a) upper part of the second shale south of the ridge of sandstone in the Rome formation ("Town Knobs"), on the road from Rogersville to Dodson Ford, near the line between the Morristown and Greeneville quadrangles (U. S. Geol. Survey), Hawkins County; (124) shales (Nolichucky?) overlying limestone which rests on Rogersville shale, on Big Creek, southeast of Harlan Knob, 4 miles (6.4 km.) northeast of Rogersville [Keith, 1905, p. 4, and areal geology sheet], Hawkins County; and (118) shales on the Tazewell road, 2 miles (3.2 km.) north of Knoxville, Knox County; all in Tennessee.

OBOLUS LOPERI Walcott.

Plate IX, figures 4, 4a.

Obolus loperi WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, pp. 389-390. (Described and discussed as below as a new species.)

General form subsemicircular, with the ventral valve subacuminate and the dorsal valve broad ovate to circular in outline. Some of the shells are more elongate than in what is considered to be the typical form. This type of variation is also observed in *O. matinalis* (Hall) (Pl. VIII) and other species of the genus. Valves moderately convex as they occur in the sandstone. Surface of the shell marked by concentric lines and fine striae of growth and very narrow radiating undulations that are more or less interrupted by the concentric lines of growth.

^a Locality 11j is given as the type locality, though the type specimens were collected from the Mine Lamotte locality long before the collection to which this number was assigned. The two localities are believed to be the same.

^b 101a is the type locality.

When the outer layer of the shell is exfoliated, the inner layers are seen to be marked by numerous fine, rounded, radiating striæ in addition to the concentric lines of growth; exceedingly fine, irregular, interrupted striæ give it in places a pitted appearance, while in a different light it appears to be granulated, a feature of the surface that seems to be present on all of the inner lamellæ: sometimes the impression given is that the shell is minutely punctate.

The markings of the interior, so far as known, are rounded radiating striæ. The shell is rather thick and built up of a thin outer layer and several inner layers or lamellæ that in the anterior portions of the shell are rounded obliquely to the outer surface.

The largest shell in the collection is a somewhat imperfect dorsal valve 8 mm. in length. A smaller valve, 6 mm. in length, has the same width. A ventral valve 6 mm. in length has the portion about the beak broken away and is a little longer than wide.

The only trace of the interior of the valves is a partial cast of the dorsal valve. This shows that the anterior lateral muscle scars were situated on the anterior portion of the valve about one-third the length of the shell from the anterior margin.

Observations.—This species resembles in many respects *O. matinalis* (Hall), especially the Texan form referred to that species. The material is poorly preserved, but it appears to be clearly distinct from any described species. Its surface characters are like those of *Obolus prindlei* (Walcott) (Pl. XXVII).

The species is named in recognition of the difficult and persevering work of Mr. S. Ward Loper, curator of the museum of Middlebury College, who made a large collection of fossils under the most adverse circumstances in the mountains of Colorado.

FORMATION AND LOCALITY.—**Passage beds** between the Upper Cambrian and the Ordovician: (335a) Reddish sandstone on Cement Creek, 3 miles (4.8 km.) north of Hot Springs and 8 to 10 miles (12.8–16 km.) southeast of Crested Butte, Ouray County, Colorado.

OBOLUS MCCONNELLI (Walcott).

Plate XXIII, figures 3, 3a (not 3b–d).^a

Lingulella mconneli WALCOTT, 1889, Proc. U. S. Nat. Mus., vol. 11, p. 441. (Described as a new species.)

Lingulella mconneli Walcott, MATTHEW, 1902, Trans. Roy. Soc. Canada, 2d ser., vol. 8, sec. 4, No. 3, p. 108. (Original description copied and species discussed.)

Obolus mconneli WALCOTT (in part), 1908, Canadian Alpine Journal, vol. 1, No. 2, p. 244, Pl. I, fig. 2 (not fig. 2a, referred in this monograph to *Obolus septalis*). (No text reference. Fig. 2 is copied in this monograph, Pl. XXIII, fig. 3a.)

General form elongate ovate with the ventral valve subacuminate and rather broadly rounded in front and obtusely rounded posteriorly. When the dorsal valve is crushed and flattened in the shale it is broadly ovate. As far as can be determined from the somewhat compressed shells the valves were moderately convex. Surface of the shell marked by concentric lines of growth and fine, irregular striæ that are more or less transverse and apparently imbricating, giving a surface a little suggestive of *Obolus (Westonia) aurora* (Hall). When the outer layer is exfoliated the surface of the inner layer is marked by concentric and radiating striæ. The interior surface is marked by rather strong radiating striæ and scattered punctæ. The shell is thick for one of its size. It is formed of a thin outer layer, several thin inner layers, and numerous lamellæ in the anterior half of the valves. The only interior vascular markings seen are those of the visceral cavity and main vascular sinuses of the ventral valve.

Observations.—Since the original description [Walcott, 1889c, p. 441] was written a few specimens have been secured that add a little to the data for the description of the species.

The broad subtrigonal form represented in Plate XXIII, figure 3a, occurs on the same slab of shaly limestone with the more elongate shell represented in figure 3. The latter is compressed laterally, which makes it appear more elongate and also strengthens the radiating striæ.

A small shell from Big Cottonwood Canyon, southeast of Salt Lake City, Utah, provisionally referred to *Lingulella helena* (Walcott) (Pl. XXIV, fig. 3d), may prove to belong to this species.

^a Figures 3b and 3c represent specimens of *Obolus mconneli pelias*. Figure 3d represents a specimen of *Obolus septalis*.

At most localities this species occurs within 200 feet of the base of the Middle Cambrian. In the House Range section of Millard County, Utah, however, it has been found at about 1,500 feet above the Middle Cambrian, and at other localities a very closely allied form, which was originally described as a species, "*Obolus (Lingulella) pelias*" [Walcott, 1905a, p. 330], occurs in the middle portion of the Middle Cambrian and extends into the Upper Cambrian. This I have now designated as the variety *pelias*. Another variety, *decipiens*, occurs in the Upper Cambrian.

The variety *pelias*, as a whole, is slightly narrower in the dorsal valve and somewhat more obtuse in the ventral valve. The variety *decipiens* is still shorter and broader in proportion as compared with the typical *Obolus mcconnelli*.

This is one of the most persistent forms in the Middle Cambrian section of the Cordilleran region, ranging, as it does, with its two varieties, from near the base of the Middle Cambrian well up into the Upper Cambrian or through 4,500 feet of limestone. It also has a wide geographic distribution in the Cordilleran region, extending from British Columbia to southeastern California.

FORMATION AND LOCALITY.—**Middle Cambrian:** (14s) About 2,300 feet (701 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian, in the *Ogygopsis* zone of the Stephen formation [Walcott, 1908f, p. 210], at the great "fossil bed" on the northwest slope of Mount Stephen, above Field, on the Canadian Pacific Railway; (57f) about 2,200 feet (670.6 m.) above the Lower Cambrian and 2,800 feet (853.4 m.) below the Upper Cambrian, in the limestones forming 1 of the Stephen formation [Walcott, 1908f, p. 209], about 0.5 mile (0.8 km.) east of the "fossil bed" on the northwest slope of Mount Stephen, above Field, on the Canadian Pacific Railway; (58j) about 1,900 feet (579 m.) above the Lower Cambrian and 3,100 feet (945 m.) below the Upper Cambrian, near the base of the limestone forming 2 of the Stephen formation [Walcott, 1908c, p. 238 (7)], on the east side of Mount Stephen about 3,000 feet (914 m.) above the Canadian Pacific Railway track 3 miles (4.8 km.) east of Field; and (58r) about 1,800 feet (548.6 m.) above the Lower Cambrian and 3,200 feet (975.4 m.) below the Upper Cambrian, in the limestones forming 2 of the Stephen formation [Walcott, 1908f, p. 211], in the amphitheater between Mounts Stephen and Dennis, above Field on the Canadian Pacific Railway; all in British Columbia, Canada.

(35g)^a About 4,100 feet (1,250 m.) above the Lower Cambrian and 860 feet (262 m.) below the Upper Cambrian in the shaly limestones in 2 of the Eldon limestone [Walcott, 1908f, p. 209 ("*Lingulella* sp.")] at the north end of the amphitheater northwest of the main ridge of Mount Bosworth; and (57c and 57k) about 2,500 feet (762 m.) above the Lower Cambrian and 2,475 feet (754 m.) below the Upper Cambrian in the limestone forming 1 of the Stephen formation [Walcott, 1908f, p. 209], on Mount Bosworth; both north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide between British Columbia and Alberta, Canada.

(58i and 58w) About 1,225 and 1,300 feet (373 and 396 m.), respectively, above the Lower Cambrian in the shales of the Stephen formation [Walcott, 1908a, p. 3], northeast slope of Castle Mountain facing the amphitheater, north of the Canadian Pacific Railway, Alberta.

(3j) Above the quartzitic sandstones in a shale corresponding in position to the upper part of shale No. 6 of the Dearborn River section [Walcott, 1908f, p. 202], about 6 miles (9.6 km.) west-northwest of Scapegoat Mountain on the Continental Divide between Bar Creek and the headwaters of the south fork of North Fork of Sun River, Coopers Lake quadrangle (U. S. Geol. Survey), Powell County, Montana.

(31c) About 900 feet (274.3 m.) above the Brigham quartzite and 3,300 feet (1,005.8 m.) below the Upper Cambrian, in the limestone forming 1b of the Ute limestone [Walcott, 1908f, p. 196]; and (54p) about 255 feet (160 m.) above the Brigham quartzite and 3,665 feet (1,127.1 m.) below the Upper Cambrian in the shales forming 2f of the Ute limestone [Walcott, 1908f, p. 197]; both in Blacksmith Fork Canyon about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

(34n) Shales about 100 feet (30.5 m.) above the Tintic quartzite [G. O. Smith, 1900, p. 1], near the summit of the ridge between Mammoth and Eureka; and (34s) about 1,700 feet (518 m.) above the Tintic quartzite in the Mammoth limestone of G. O. Smith [1900, p. 1, and historical geology sheet], in the saddle above and a little east of the Centennial Eureka mine, near the summit of the ridge between Mammoth and Eureka; both in the Tintic special quadrangle (U. S. Geol. Survey), Juab County, Utah.

(30p) About 125 feet (38 m.) above the Cambrian quartzitic sandstones, on the north side of Ogden Canyon, about 1 mile (1.6 km.) above its mouth, east of Ogden, Weber County; and (31y) thin-bedded limestone about 125 feet (38 m.) above the Cambrian quartzitic sandstones in the Wasatch Mountains, 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County; both in Utah.

(10y) About 2,900 feet (884 m.) above the Lower Cambrian and 1,500 feet (457.2 m.) below the Upper Cambrian in the central part of the limestone forming 1a of the Marjum limestone [Walcott, 1908f, p. 179], about 1 mile (1.6 km.) south-southwest of Marjum Pass; and (14v) shales of unknown stratigraphic horizon collected 1 mile (1.6 km.) south of Rainbow Valley; both in the House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.

(8m) Limestone near the south end of the high ridge 4 miles (6.4 km.) northeast of Osceola; and (10w) shaly limestones about 5 miles (8 km.) northeast of Osceola, on the east side of the Snake Range; both in White Pine County, Nevada.

^a This species is somewhat doubtfully identified from this locality.

(14n) Limestone about 310 feet (94.5 m.) above the Lower Cambrian on the east side of the pass about 7 miles (11.2 km.) east of Resting (Freshwater) Springs, which is in the southwest corner of T. 21 N., R. 8 E., on Amargosa River, in the southeastern part of Inyo County, California.

Middle? Cambrian: (32k) Limestones about 1,550 feet (472.4 m.) above the top of the quartzitic sandstones 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah.

OBOLUS MCCONNELLI DECIPIENS n. var.

Plate XXIII, figures 4, 4a-b.

A form that appears to be a broad variety of *Obolus mconnelli* (Walcott) occurs abundantly in the arenaceous shales and interbedded limestone of the Upper Cambrian of the Silver Peak Range, Esmeralda County, Nevada. Most of the material is badly preserved, and some of the specimens afford fine illustrations of distortion of outline by compression. The variety differs from the species in being uniformly broader and also in having more strongly marked concentric striæ. It differs from the variety *pelias* in being of an average greater proportional width.

FORMATION AND LOCALITY.—**Upper Cambrian:** Emigrant formation [Turner, 1902, p. 265] at the following localities: (7v) shales 4.25 miles (6.8 km.) south-southeast of Emigrant Peak; (7x) limestone about 2.5 miles (4 km.) southeast of Emigrant Pass; and (8r) shales about 8 miles (12.8 km.) southeast of Emigrant Peak; all in the Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County, Nevada.

Middle Cambrian: (7r) Calcareous shales 4 miles (6.4 km.) south-southeast of Emigrant Peak, Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County; and (8m) limestone near the south end of the high ridge 4 miles (6.4 km.) northeast of Osceola, White Pine County; both in Nevada.

(14n) Limestone about 310 feet (94.5 m.) above the Lower Cambrian on the east side of the pass about 7 miles (11.2 km.) east of Resting (Freshwater) Springs, which is in the southwest corner of T. 21 N., R. 8 E., on Amargosa River, in the southeastern part of Inyo County, California.

OBOLUS MCCONNELLI PELIAS (Walcott).

Plate XXIII, figures 3b, 3c; Plate XXXIX, figures 5, 5a-c.

Obolus (Lingulella) pelias WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 330-331. (Described and discussed as a new species.)

This form was originally described [Walcott, 1905a, pp. 330-331] as a distinct species, but, with the large collections obtained in 1906 from various horizons of the Middle Cambrian, it is found to have close relations to *Obolus mconnelli* of the lower portion of the Middle Cambrian. It ranges from about the central portion of the Middle Cambrian up into the Ordovician.

The variety differs from *O. mconnelli* in being proportionally shorter and broader, and from the variety *decipiens*, of the Upper Cambrian, in being, on the average, slightly narrower.

The outer surface of the shell is marked by clearly defined concentric lines that are slightly irregular, and narrow, fine, radiating undulations or costæ toward the frontal margins. When unusually well preserved, the surface also shows very fine, irregular, concentric striæ between the concentric lines. The inner lamellæ of the shell are marked by fine radiating striæ and the inner surface by more or less numerous punctæ. For its size the shell may be considered as relatively thin.

FORMATION AND LOCALITY.—**Upper Cambrian:** (54r) Drift pieces of limestone from the west slope of the Wasatch Range; and (34q) shales about 3,800 feet (1,158.2 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in Wasatch Canyon; both east of the Lakeview Ranch, about 5 miles (8 km.) north of Brigham, Boxelder County, Utah.

(32g) About 2,575 feet (784.9 m.) above the Cambrian quartzitic sandstones in a blue limestone about 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County; (33d) thin-bedded blue limestone at the base of the first high point southwest of the J. J. Thomas ranch, on the east side of the Fish Spring Range, Juab County; and (30j) about 950 feet (289.6 m.) above the Middle Cambrian and 2,450 feet (746.8 m.) below the top of the Upper Cambrian near the base of the arenaceous shales and limestones forming 1e of the Orr formation [Walcott, 1908f, p. 176], on Orr Ridge, about 5 miles (8 km.) south of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County; all in Utah.

(7s) Shale of the Emigrant formation [Turner, 1902, p. 265], 4 miles (6.4 km.) south-southeast of Emigrant Peak, Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County, Nevada.

Middle Cambrian: (8j) About 575 feet (175.3 m.) above the unconformable base of the Cambrian in a shale which corresponds in position to shale No. 4 of the Dearborn River section [Walcott, 1908f, p. 202], on the ridge between

Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. Geol. Survey), Powell County, Montana.

(15p) Limestones near the north end of the Fish Spring Range, Tooele County; and (15x) limestones near the middle of the Fish Spring Range, near the line between Juab and Tooele counties; both in Utah.

(11n) About 3,000 feet (914.4 m.) above the Lower Cambrian and 1,400 feet (426.7 m.) below the Upper Cambrian in the upper part of the limestone forming Ia of the Marjum limestone [Walcott, 1908f, p. 179], in the long cliff 2 miles (3.2 km.) southeast of Marjum Pass; (11o) about 2,750 feet (838.2 m.) above the Lower Cambrian and 1,650 feet (502.9 m.) below the Upper Cambrian, at the base of the limestone forming Ia of the Marjum limestone [Walcott, 1908f, p. 179], about 4 miles (6.4 km.) southeast of Antelope Springs in the spur at the junction of the Deseret and Swasey Spring roads; (11q and 30g)^a about 2,350 feet (716.3 m.) above the Lower Cambrian and 2,050 feet (624.8 m.) below the Upper Cambrian in the limestone forming 1c of the Marjum limestone [Walcott, 1908f, p. 180], ridge east of Wheeler Amphitheater; (3x and 3y) about 2,200 feet (670.6 m.) above the Lower Cambrian and 2,200 feet (670.6 m.) below the Upper Cambrian in the limestones forming 1d of the Marjum limestone [Walcott, 1908f, p. 180], ridge east of Wheeler Amphitheater; (3s and 8g) about 1,700 feet (518.2 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian in the shaly limestones and calcareous shales of the Wheeler formation [Walcott, 1908f, p. 181], in the eastern part of Wheeler Amphitheater east of Antelope Springs; (8i) shales believed to be referable to the lower portion of the Marjum limestone [Walcott, 1908f, p. 180], found about 0.5 mile (0.8 km.) east of Antelope Springs; and (8k) shales 0.5 mile (0.8 km.) northwest of Tyler Springs, east slope of House Range east of Antelope Springs; all in the House Range [Walcott, 1908f, Pls. XIII and XV], Millard County, Utah.

(54h) About 3,140 feet (957.1 m.) above the Brigham quartzite and 1,050 feet (320 m.) below the Upper Cambrian in the limestones forming 1a of the Bloomington formation [Walcott, 1908f, p. 194], in Blacksmith Fork Canyon, about 9 miles (14.4 km.) east of Hyrum, Cache County, Utah.

Middle? Cambrian: (34v) Limestone about 1,750 feet (533 m.) above the Cambrian quartzitic sandstones about 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range, Tooele County, Utah.

OBOLUS MÆRA (Hall and Whitfield).

Plate X, figures 2, 2a-e.

Lingulepis mæra HALL and WHITFIELD, 1877, U. S. Geol. Expl. 40th Par., vol. 4, p. 206, Pl. I, figs. 5-7. (Described and discussed as a new species. The specimens represented by figs. 6 and 5 are redrawn in this monograph, Pl. X, figs. 2a and 2b, respectively.)

Lingulepis mæra Hall and Whitfield, WALCOTT, 1884, Mon. U. S. Geol. Survey, vol. 8, pp. 12-13. (New localities mentioned.)

Lingulella? *mæra* (Hall and Whitfield), HALL and CLARKE, 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 61. (Suggests change in generic reference.)

Lingulella? *mæra* (Hall and Whitfield), WALCOTT, 1897, Am. Jour. Sci., 4th ser., vol. 3, p. 404. (Merely changes generic reference.)

Obolus (*Lingulella*) *mæra* (Hall and Whitfield), WALCOTT, 1899, Mon. U. S. Geol. Survey, vol. 32, pt. 2, p. 443. (Merely changes generic reference.)

General form round ovate, with the ventral valve broadly subacuminate and the dorsal valve obtusely rounded; valves rather strongly convex, the convexity increasing gradually from the margins to the umbonal portion of the shell, where it is greatest. Surface marked by concentric lines and fine striæ of growth and very fine indistinct radiating striæ that can be seen only with a strong glass in a reflected light. When the outer layer of the shell is exfoliated the surface is marked by numerous radiating striæ, becoming coarser toward the front, where they outline narrow, slightly raised ribs; this latter feature varies from simple radiating striæ to the appearance of narrow ribs; the interior surface has not been seen. The shell is formed of a rather thin outer layer and numerous inner layers, which make a strong, thick shell; the inner lamellæ over the anterior portions of the shell are oblique to the outer layer and when the shell is partly exfoliated appear as imbricating layers. A small ventral valve 10 mm. in length has a width of 8 mm. A larger associated dorsal valve has a length of 11 mm., width of 10 mm.

The only portion of the interior of the shell thus far discovered is an imperfect cast of a portion of the area of a ventral valve (Pl. X, fig. 2).

Observations.—This species is most nearly related to *O. matinalis* (Hall) (Pl. VIII). It differs from that in being somewhat more elongate, although some examples vary but little from *O. matinalis*. The fact that it occurs in the Upper Cambrian near the base of the Ordovician has more influence in leaving it as a distinct species than any differences which have been thus far observed.

^a 11q is the type locality.

The species is quite widely distributed. The type came from the thin-bedded limestones in the Dunderberg shale, at the summit of the Cambrian in the Eureka district, Nevada. T. W. Stanton found what appears to be the same species in sandy shales and sandstones at Glenwood Springs, Colorado. A partly exfoliated, somewhat distorted ventral (?) valve from an Upper Cambrian limestone one mile south-southwest of Highgate Falls, Vermont, appears to be identical with *O. mæra*.

FORMATION AND LOCALITY.—**Passage beds** between the Upper Cambrian and the Ordovician: (205) Siliceous limestone on Roundtop Mountain, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

Upper Cambrian: (313) [Hall and Whitfield, 1877, pp. 205 and 206] Limestone in the Eureka district; and (61) limestones in the Dunderberg shale [Walcott, 1908f, p. 134], a little south of the Hamburg mine; both in the Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

(360h) Sandy shales about 200 feet (61 m.) above the base of the section at Glenwood Springs; and (360i) Sandstone about 100 feet (30.5 m.) above the base of the section at Glenwood Springs; both in Garfield County, Colorado.

Middle Cambrian: (58) shaly limestones in upper beds of Secret Canyon shale, east side of New York and Secret canyons, Eureka County, Nevada.

A specimen that is somewhat doubtfully referred to *Obolus mæra* occurs at the following locality:

Upper Cambrian: (319q) Limestone 1 mile (1.6 km.) south-southwest of Highgate Falls, Franklin County, Vermont.

OBOLUS MATINALIS (Hall).

Plate VIII, figures 1, 1a-k.

Orbicula prima OWEN, 1852, Rept. Geol. Survey Wisconsin, Iowa, and Minnesota, p. 583, Pl. I B, figs. 13 and 16-19. (Described as a new species.)

Lingulepis pinnaformis HALL (in part) [not (OWEN)], 1863, Sixteenth Ann. Rept. New York State Cab. Nat. Hist., pp. 129-130, Pl. VI, figs. 12 and 13 (not figs. 14-16, referred to *Lingulella (Lingulepis) acuminata*). (The specimens represented by figs. 12, 13, and 15 are referred with doubt to "*Lingulepis pinnaformis*" and the name *matinalis* is proposed for them on p. 130 in the event of their proving distinct. The specimen represented by fig. 15 is a dorsal valve of the true "*Lingulepis pinnaformis*"=*Lingulella (Lingulepis) acuminata*. See following reference.)

Lingulepis matinalis HALL, 1863, idem, p. 130, Pl. VI, figs. 12 and 13 (not fig. 15, referred to *Lingulella (Lingulepis) acuminata*). (The specific name *matinalis* is proposed for the forms represented by figs. 12, 13, and 15 should they prove distinct from those represented by figs. 14 and 16. See preceding reference.)

Lingulepis pinnaformis HALL (in part) [not (OWEN)], 1867, Trans. Albany Inst., vol. 5, p. 107, Pl. I, figs. 12 and 13 (not figs. 14-16). (Copy of Hall, 1863, pp. 129-130, Pl. VI, figs. 12 and 13; see note following citation above.)

Lingulepis matinalis HALL, 1867, idem, p. 107, Pl. I, figs. 12 and 13 (not fig. 15). (Copy of Hall, 1863, Pl. VI, figs. 12 and 13; see note following citation above.)

Lingulella? matinalis (Hall), WALCOTT, 1897, Am. Jour. Sci., 4th ser., vol. 3, p. 404. (Merely changes generic reference.)

Obolus (Lingulella) matinalis (Hall), WALCOTT, 1899, Mon. U. S. Geol. Survey, vol. 32, pt. 2, p. 443. (Merely changes generic reference.)

General form rounded ovate, with the ventral valve broadly subacuminate and the dorsal valve obtusely rounded; valves rather strongly convex, convexity increasing gradually from the margins to the central portion of the shell. Surface of the shell marked by concentric lines and striæ of growth and faint interrupted radiating striæ; the finer concentric striæ fill in the interspaces between the lines of growth. When the outer layer of the shell is exfoliated, the surface is marked by numerous fine, radiating striæ (Pl. VIII, fig. 1a), and with more or less obscure concentric lines of growth; the radiating striæ are particularly strong over the anterior portion of the inner oblique layers or lamellæ of the shell. As far as can be determined from the casts of the inner surface it was marked by concentric lines of growth and strong, radiating, flattened striæ (Pl. VIII, fig. 1e). The shell is formed of a thin outer layer and numerous inner layers or lamellæ over the anterior and outer portions; these inner lamellæ over the anterior portions of the shell are oblique to the outer layer, and when the shell is partly exfoliated they appear as imbricating layers, as shown by Plate VIII, figure 1c; the layers of lamellæ over the umbo and central portions are strong and give a considerable thickness to the shell. The species vary somewhat in size and in the outline of the valves, as may be seen by comparing the various figures. A ventral valve 11 mm. in length has a width of 11.5 mm.; another ventral

valve 11.5 mm. in length has a width of 11 mm. A dorsal valve 9 mm. in length has a width of 9 mm.; another dorsal valve 11 mm. in length has a width of 12 mm.

Casts of the interior of the ventral valve show a very clearly defined area of medium length (Pl. VIII, fig. 1d); it is divided midway by the cast of a strong pedicle groove and about halfway between the groove and the lateral margin by a distinct flexure line; striæ of growth cross the area parallel with its front margin, being flexed on the flexure line and arching over the cast of the pedicle groove. None of the casts show whether the area formed a shelf between the pedicle groove and the lateral margins, as in most species of the genus *Lingulella*. The area of the dorsal valve is short and relatively narrow, extending about halfway out on the cardinal slopes.

The cast of the visceral cavity of the ventral valve is well shown by several specimens (Pl. VIII, figs. 1d and 1e). It resembles that of *Obolus apollinis quenstedti* (Mickwitz) in having the anterior margins extending almost directly outward from the center toward the impressions of the main vascular sinuses. There are no traces of a median septum in the ventral valve; in the dorsal valve it is shown in the cast as a very narrow depression and between and a little forward of the central muscle scars (Pl. VIII, fig. 1h). The thickening of the shell at the anterior margin of the visceral cavity of the ventral valve is quite marked, as shown in Plate VIII, figure 1f.

The muscle scars are well shown in one specimen of the ventral valve (Pl. VIII, fig. 1f). The central (h), middle (k), and outside lateral (l) scars occur, but usually the scars can not be differentiated. The anterior lateral (j) and transmedian (i) scars are also quite distinctly shown. In the dorsal valve (Pl. VIII, fig. 1h) the central (h) and anterior lateral (j) scars are clearly defined, also the transmedian (i) scars. Of the markings left on the shell by the vascular system the main vascular sinuses are usually well shown in the casts, and in one specimen of the ventral valve both the inner and lateral branches are finely outlined (Pl. VIII, fig. 1d).

The parietal sear (ps) is nearly transverse in front of the visceral area of the ventral valve; it arches forward at the center and curves a little backward toward the main vascular sinuses. Its course outside of the latter is partly shown by Plate VIII, figure 1d. In the dorsal valve its course may be followed from the median line in front of the anterior lateral scars to the outward curve of the trunk sinuses, beyond which it can not be traced with any degree of certainty.

Observations.—This species has not heretofore been well described or illustrated. Hall [1863, p. 130] noticed that there were certain ovate shells associated with "*Lingulepis pinnaformis*" which had a smooth, glossy surface, with fine concentric striæ, and that when the outer surface was removed it was very distinctly striated by fine, somewhat bifurcating striæ. In accordance with the system in vogue at that time he proposed, in event of the form proving to be a distinct species, to have it called *Lingulepis matinalis*. A smaller shell occurs in association with *Dicellomus politus* (Hall) at Eau Claire, Wisconsin, that appears to be identical with *O. matinalis*. It differs in having smaller central muscle scars in the dorsal valve, but, as the variation in form and size of the muscle scars is often considerable in shells of the same species, this is not considered sufficient for specific differentiation.

The Texas shells from Packsaddle Mountain (Pl. VIII, figs. 1l-o) are smaller than the typical Wisconsin forms, and are identified with *Obolus tetonensis ninus* (Pl. XI, figs. 1, 1a-g). The specimens represented in Plate VIII, figures 1b, 1e, and 1h, are larger and more readily identified with the species. A single ventral valve from the Bighorn Mountains is similar in form to ventral valves from Texas. At La Crosse, Wisconsin, the shells are smaller and occur about 200 feet below the base of the arenaceous limestone of the Ordovician.

This species appears to be distinct from any described form. It approaches most nearly to *O. mæra* (Hall and Whitfield), differing from the latter in being slightly less elongate.

FORMATION AND LOCALITY.^a—**Lower Ordovician:** (360a) Red siliceous limestone on west side of Trout Creek below Bergen Park, 7 miles (11.2 km.) north-northwest of Manitou, El Paso County, Colorado.

Upper Cambrian: (302d) Limestone 200 yards (183 m.) north of the southwest corner of sec. 18, T. 28 N., R. 113 W., Uinta County, Wyoming.

^a Owen [1852, p. 583] gives the type locality as "falls of the St. Croix, Minnesota;" this might be compared with our localities 328h, 328s, and 328e, all in Wisconsin.

(82b) "St. Croix sandstone" along the railroad track near Taylors Falls, Chisago County; (339d) "St. Croix sandstone" at Taylors Falls, Chisago County; (339f) "St. Croix sandstone" near Minneiska (Miniska) on Mississippi River near the line between Wabasha and Winona counties; (97b) "St. Croix sandstone" below the green-sand bed and 25 feet (7.6 m.) above St. Croix River at Franconia, Chisago County; and (339h [Hall, 1863, p. 130]) "St. Croix sandstone" at the mouth of Minneiska (Miniska) River, near the line between Wabasha and Winona counties; all in Minnesota.

(328h) Silico-calcareous layers of F1b of Owen [1852, p. 583], at the falls of St. Croix River, Polk County; (100) "St. Croix sandstone" near Menomonie, Dunn County; (134) "St. Croix sandstone" in the lowest beds exposed along the banks of Red Cedar River, opposite Menomonie, Dunn County; (82a) "St. Croix sandstone" 25 feet (7.6 m.) above the water level near the Knapp, Stout and Company's buildings, Menomonie, Dunn County; (82s) "St. Croix sandstone" on the bank of St. Croix River at St. Croix Falls, Polk County; (79, 79', and 79b) "St. Croix sandstone" near Hudson, St. Croix County; (83) "St. Croix sandstone" near Trempealeau, Trempealeau County; (78d) upper portion of "St. Croix sandstone" exposed in the bluffs at La Crosse, La Crosse County; and (98 and 98x) "St. Croix sandstone" near Eau Claire, Eau Claire County; all in Wisconsin.

(9t) About 170 feet (52 m.) above the porphyry contact in the limestones of the Reagan sandstone, SE. $\frac{1}{4}$ NE. $\frac{1}{4}$ sec. 2, T. 4 N., R. 13 W., 15 miles (24.2 km.) northwest of Fort Sill, Comanche County, Oklahoma.

(14e) Limestone in Bartlett Hollow, 2 miles (3.2 km.) southeast of the mouth of Falls Creek, Burnet quadrangle (U. S. Geol. Survey), Lampasas County; (68 and 68z) limestone on Packsaddle Mountain, Llano County; (14b) limestone on Cold Creek at north end of gorge opposite the north end of Sponge Mountain, 2 miles (3.2 km.) south of the San Saba County line, in Llano County; (14c) upper part of the limestone exposed at Baldwin's ranch, on Cold Creek, 2.5 miles (4 km.) south of the San Saba County line, in Llano County; (67, 67c, and 67z) sandstone on Tatur Hill, 7 miles (11.2 km.) northwest of Burnet, Burnet County; (14q) sandstone in Bartlett Hollow, 1.5 miles (2.4 km.) southeast of the mouth of Falls Creek, Burnet quadrangle (U. S. Geol. Survey), Lampasas County; (14r) lower 50 feet of sandstone on Colorado River, 3 miles (4.8 km.) south of the northeast corner of Llano County; and (71) limestone in Cold Creek Canyon, Burnet County; all in Texas.

(92b) On Buffalo Creek, 2 miles (3.2 km.) southeast of Buffalo Mills, Rockbridge County, Virginia.

Middle Cambrian: (302) Limestone east of West Gallatin (Gallatin) River, above Gallatin, Gallatin County, Montana.

(170) Sandstone about 10 miles (16.1 km.) south-southeast of Bald Mountain, Bighorn Mountains, Wyoming.

(56f) Nounan limestone [Walcott, 1908a, p. 6], on a ridge north of the creek which flows into Mill Canyon from the west, about 5 miles (8 km.) west-southwest of Liberty and 15 miles (24.2 km.) west of Montpelier, Bear Lake County, Idaho.

(3e) Thin-bedded limestone less than 400 feet (121.9 m.) above the quartzitic sandstones of the Cambrian, at Ophir, Oquirrh Range, Tooele County, Utah.

(328e) "St. Croix sandstone" at St. Croix Falls, Polk County; and (83') St. Croix sandstone at Trempealeau, Trempealeau County; both in Wisconsin.

Specimens somewhat doubtfully referred to *Obolus matinalis* occur at the following localities:

Upper Cambrian: (11d) Arenaceous limestone about 2 miles (3.2 km.) north of Montana, in sec. 22, T. 35 N., R. 1 E., Iron County, Missouri.

Middle Cambrian: (319s) "St. Albans formation" at St. Albans, Franklin County, Vermont.

(11e) Thin-bedded limestones south-southwest of Potosi, Washington County, Missouri.

OBOLUS MATINALIS (Hall) ?

Plate VIII, figures 3, 3a.

(For synonymy of *Obolus matinalis*, see page 400.)

Obolus matinalis (Hall)?, WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 325. (Mentioned as below.)

A form indistinguishable from this species occurs in China in a gray limestone of Upper Cambrian age. Only the general form of partly exfoliated shells is known.

FORMATION AND LOCALITY.—**Upper Cambrian:** (C54) Lower part of Chaumitien limestone [Blackwelder, 1907a, p. 42 (part of last list of fossils)], near top of limestone knoll, 0.66 mile (1.1 km.) west of Tsinan, Shantung, China.

OBOLUS MEMBRANACEUS Walcott.

Text figures 36A-E, page 403.

Obolus membranaceus WALCOTT, 1908, Smithsonian Misc. Coll., Vol. LIII, No. 3, p. 61, Pl. VII, fig. 11. (Characterized and discussed as below as a new species. Fig. 11 is copied as fig. 36A in this monograph.)

In size and outline this species is somewhat similar to *Obolus feistmanteli* (Barrande) (Pl. XII, figs. 1, 1a-c), but in its very thin almost membranaceous shell it differs from that species and

all other species of the genus known to me. Seven specimens were collected from a shaly compact limestone, all as casts. Remnants of the corneous shell are preserved, which show it to have been very thin, and the interior casts show that it did not retain any impressions of the animal sufficiently strong to be impressed on the cast. A short, rather narrow cardinal area occurs on both the ventral and dorsal valves. Outer surface smooth, with a few lines of growth. The largest ventral valve has a length of 17 mm. and a width of 22 mm. A less distorted dorsal valve has the same length and width, 15 mm.

The specific name was given because of the very thin almost membranaceous shell.

FORMATION AND LOCALITY.—Middle Cambrian (35g): About 4,100 feet (1,250 m.) above the Lower Cambrian and 860 feet (262 m.) below the Upper Cambrian in the shaly limestones in No. 2 of the Eldon limestone, at the north end of the amphitheater north-west of the main ridge of Mount Bosworth, north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide, between British Columbia and Alberta, Canada.

FIGURE 36.—*Obolus membranaceus* Walcott. A, Cast of ventral valve (U. S. Nat. Mus. Cat. No. 53674a). B, Cast of dorsal valve (U. S. Nat. Mus. Cat. No. 53674b). Both natural size.

The specimens represented are from Locality 35g, Eldon limestone on Mount Bosworth, British Columbia. Figure 36A is copied from Walcott [1908d, Pl. VII, fig. 11]; it represents the type specimen.

OBOLUS? MENEGHINII Walcott.

Plate XXX, figures 17, 17a.

Not *Lingula petalon* (HICKS MS.) DAVIDSON, 1868, Geol. Mag. vol. 5, p. 308, Pl. XV, fig. 16. (Not taken up in this monograph.)

Not *Lingula petalon* DAVIDSON, 1871, British Fossil Brachiopoda, vol. 3, pt. 7, No. 4, p. 337, Pl. XLIX, fig. 30. (Not taken up in this monograph.)

Lingula petalon BORNEMANN [not DAVIDSON], 1891, Nova Acta Acad. Cæs. Leop.-Carol. Germanicæ Naturæ Curiosorum, Bd. 56, No. 3, p. 438, Pl. XIX (XXXIV), figs. 12-14. (Described in German; see below for translation. Fig. 14a is copied in this monograph, Pl. XXX, fig. 17.)

Obolella sp. (?) BORNEMANN, 1891, idem, p. 440, Pl. XIX (XXXIV), fig. 18. (Characterized in German. Fig. 18 is copied in this monograph, Pl. XXX, fig. 17a.)

Obolus (?) *meneghini* WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 684. (Bornemann's description, 1891, p. 438, translated, and species discussed as below as a new species.)

Bornemann says [1891, p. 438]:

Rounded triangular, frontal margin at times almost straight. Shells rather flat, their arching being greatest in the middle. Concentric and rather coarse lines of growth. Size, 5-11 mm.

The specimen referred to "*Obolella* sp. (?)" by Bornemann [1891, p. 440] is from the slate of Porto Canal Grande. It is not an *Obolella* and may be identical with the species from the sandstones.

The shells referred to "*Lingula petalon*" [Bornemann, 1891, p. 438] suggest *Obolus* in form and surface ornamentation and are tentatively referred to that genus and a specific name given them in recognition of the work of Prof. Giuseppe Meneghini.

FORMATION AND LOCALITY.—Middle Cambrian: (354c) Yellow, friable sandstone at Punta Pintau (Canal Grande); (354d) yellow friable sandstone at Gruguetta; and (354e) slate at Porto Canal Grande; all [Bornemann, 1891, pp. 438 and 440] in the island of Sardinia, Italy.

OBOLUS MICKWITZI Walcott.

Plate X, figures 1, 1a-k.

Obolus mickwitzi WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, pp. 386-387. (Described and discussed as below as a new species.)

General form rounded ovate, with the ventral valve broadly subacuminate, and the dorsal valve obtusely rounded; valves, as shown by the casts, moderately convex, which would give a rather strongly convex shell, as fragments show that it was quite thick over the central portions. Fragments of the shell showing the outer surface indicate that it was marked by concentric lines and striæ of growth; radiating striæ may have been present; they are strongly developed when the outer surface is exfoliated. The casts of a number of examples of the

interior of the valves show very strong concentric undulations and lines of growth, although in some specimens these characters are scarcely perceptible. The fragments of the shell preserved show that it was formed of a thin outer layer, several inner layers or lamellæ of varying thickness, and numerous lamellæ over the anterior and lateral portions of the shell that are slightly oblique to the outer surface. A somewhat rounded ventral valve has a length of 9 mm., width 9 mm.; a dorsal valve 9 mm. long has a width of 8 mm.; a more elongate ventral valve is 9 mm. in length and 8 mm. in width; an associated dorsal valve 7.5 mm. in length has a width of 7 mm.

Casts of the interior of the ventral valve show an area of medium length, divided midway by the cast of a strong, rather broad pedicle furrow, and again a short distance each side of the pedicle furrow by a narrow, sharp, flexure line; striæ of growth cross the area of the pedicle furrow parallel with the front margin. There is slight evidence in one of the casts that the area formed a shelf between the pedicle groove and the lateral margin. The area of the dorsal valve is of medium length and fairly well extended out onto the cardinal slopes (Pl. X, fig. 1d). The cast of the visceral cavity of the ventral valve is well shown by several specimens (Pl. X, figs. 1a, 1b, and 1c). It resembles that of *Obolus matinalis* (Hall) and *O. apollinis quenstedti* (Mickwitz) in the extension of the anterior margins almost directly outward from the center toward the impression of the main vascular sinuses; one of the peculiarities of the species is the great development of the area within the parietal scar (splanchnocœle); in some examples (Pl. X, figs. 1a and 1b) it occupies all the central portions of the shell, extending to within a short distance of the frontal margin. In others it is limited to the posterior half of the shell; the same features occur in the dorsal valve (Pl. X, figs. 1d, 1e, and 1f). There are no traces of a median septum in the ventral valve; in the dorsal valve it is shown in the cast as a very narrow depression between and a little forward of the central muscle scars.

In the ventral valve the anterior lateral muscle scars are distinctly shown, also the trapezoidal area, in which the central, middle lateral, and outside lateral scars occur. In the dorsal valve (Pl. X, figs. 1d and 1g) large central (h) and small anterior lateral (j) scars are clearly defined, also the transmedian (i) scars. Of the markings left on the interior of the shell by the vascular system, the trunk sinuses are usually strongly defined in the smaller shells, extending nearly to the anterior margin, and in the larger shells about three-fourths of the way over the area to the frontal margin.

Owing to the condition of the casts of the interior, the parietal scar is usually not well defined; in the ventral valve it appears to extend from where it arches forward at the center, almost directly outward to the trunk sinuses, where it curves backward across the sinus and outside of the anterior lateral muscle scars; in the dorsal valve it extends from over the median line in front outward and backward around the side of the large central muscle scar, where it curves outward across the trunk sinuses.

Observations.—Attention has been called to the relatively large size of the visceral cavity (splanchnocœle) in both valves of the smaller shells. The range of variation in this respect is so great that it might be accepted as indicating a distinct species if there were not shells intermediate in size in which the splanchnocœle is also intermediate in proportional size. Another marked character in the specimens is the very strong impressions in the cast of the trunk sinuses and muscle scars and visceral markings. This species is somewhat more rounded in outline than *O. mæra* (Hall and Whitfield) and *O. matinalis* (Hall), and it is very distinctly marked by the muscle scars of the dorsal valve.

The specific name was given in honor of Dr. A. Mickwitz.

FORMATION AND LOCALITY.—Upper Cambrian: (79, 79', and 79b)^a "St. Croix sandstone," near Hudson; and (328j) "St. Croix sandstone" on Willow River, near Hudson; both in St. Croix County, Wisconsin.

OBOLUS MINIMUS Walcott.

Plate XI, figures 8, 8a.

Obolus minimus WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 325-326. (Described as below as a new species.)

This is a small shell of the general form of *Obolus shansiensis* Walcott. The ventral valve is obtusely acuminate and the dorsal nearly circular; valves gently convex. Surface marked by

^a 79 is the type locality.

rather strong concentric lines of growth and numerous very fine concentric striæ. The inner layers of shell are shiny black and ornamented with numerous fine, radiating striæ and concentric lines. Shell built up of several thin layers or lamellæ that form a thin shell over the umbonal region that gradually thickens as the short, oblique lamellæ become more numerous toward the front and side margins. The three specimens in the collection average 3 mm. in transverse diameter; the ventral is a little longer than the dorsal valve.

A partly exfoliated ventral valve shows a well-marked visceral area, extending forward about one-third of the length of the shell; also narrow main vascular sinuses starting near the apex and extending obliquely forward well into the valve, about midway between the median line of the valve and the lateral margins. This neat little shell is distinguished by its nearly circular outline, low convexity, and small size.

FORMATION AND LOCALITY.—**Middle Cambrian:** (C1) Lower shale member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 40 (part of the 3d list of fossils), and fig. 10 (bed 4), p. 38], 2 miles (3.2 km.) south of Yenchuang, Sintai district, Shantung, China.

OBOLUS? MINOR Barrande.

Plate XV, figure 6

Obolus? minor BARRANDE, 1868, Faune silurienne des environs de Hof, en Bavière. p. 105, fig. 68. (Described in French as a new species. Fig. 68 is copied in this monograph, Pl. XV, fig. 6.)

Obolus? minor BARRANDE, 1868, Neues Jahrb. für Mineralogie für 1868, p. 693, unnumbered plate, fig. 69. (Text and figure copied from preceding reference.)

Of this species the author [1868a, p. 105] remarks:

We know only the impression figured. It differs from *O.? palliatus* Barrande by having a well-marked beak and in being rather more elongate. The surface is ornamented by rather close concentric striæ regularly spaced. Length 7 mm., width 7 mm.

It is not improbable that this represents the ventral valve of *O.? palliatus*, but in the absence of specimens for comparison it is left with the designation given by Barrande.

FORMATION AND LOCALITY.—**Passage beds** between the Upper Cambrian and the Ordovician: (303c [Barrande, 1868a, p. 105]) suburbs of Hof, Bavaria, Germany.

OBOLUS? MIRANDUS (Barrande).

Plate XII, figures 4, 4a.

Lingula? miranda BARRANDE, 1879, Système silurien du centre de la Bohême, vol. 5, Pl. CXI, figs. 1: 1-3. (No text reference. Figs. 3A and 1a are copied in this monograph, Pl. XII, figs. 4 and 4a, respectively.)

In form this species is much like that of *Obolus ancillus* (Barrande) (Pl. XII). The traces shown of the interior markings by figure 4a are similar to those of *Obolus feistmanteli* (Barrande) (Pl. XII, fig. 1). The outer surface, as shown on the figure, recalls that of *O. (Westonia) ella* (Hall and Whitfield) (Pl. XLVII). With only the two illustrations given by Barrande, it is impossible more than provisionally to refer the species to *Obolus*.

FORMATION AND LOCALITY.—**Lower Ordovician:** (303k [Barrande, 1879b, pl. CXI]) Étage d1 at Hradischt, Bohemia, Austria-Hungary.

OBOLUS? MURRAYI Billings.

Plate XV, figure 12.

Obolus? murrayi BILLINGS, 1865, Geol. Survey Canada, Paleozoic Fossils, vol. 1, p. 362. (Described as a new species; see below for copy. The type specimen upon which Billings based his description, but which he did not figure, is represented in this monograph, Pl. XV, fig. 12.)

The original description by Billings follows:

The specimen is very nearly circular, broad ovate, width a little greater than the length, uniformly and moderately convex; the shell black and corneous and covered with fine concentric striæ. Length, 7 lines; width, about 8 lines. Of this species only a single valve was found. * * * It belongs probably to the Quebec group.

This appears to be a true *Obolus*, as far as can be determined from the exterior surface of a single specimen. Its large size and strong concentric striæ indicate that Billings's reference to the "Quebec group" (Lower Ordovician) is probably correct.

The specific name was given in honor of Alex. Murray, who discovered the specimen.

FORMATION AND LOCALITY.—**Lower Ordovician:** (314g [Billings, 1865b, p. 362]) A loose piece of gray argillaceous limestone at Maiden Arm, Hare Bay, on the east side of the northern point of Newfoundland.

OBOLUS NAMOUNA Walcott.

Plate VIII, figures 2, 2a.

Obolus namouna WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 390. (Discussed as below as a new species.)

This form is closely related to *O. matinalis* (Hall). It differs mainly in the internal character of the dorsal valve (Pl. VIII, fig. 2a). The area, in addition to the narrow area of *O. matinalis*, extends its lines of growth nearly one-fifth the length of the shell. The visceral area is shorter also than in *O. matinalis*, the central and anterior lateral scars being closer together. Owing to the somewhat imperfect character of the ventral valve, no special points of difference with the ventral valve of *O. matinalis* can be determined. It is associated on the same slabs of sandstone with *O. rhea* Walcott.

FORMATION AND LOCALITY.—**Upper Cambrian:** (98) "St. Croix sandstone" near Eau Claire, Eau Claire County, Wisconsin.

Middle Cambrian: (84) "St. Croix sandstone" at Dresbach, opposite the mouth of Black River, Winona County, Minnesota.

OBOLUS NUNDINA Walcott.

Plate XI, figures 4, 4a.

Obolus nundina WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 326. (Characterized and discussed as below as a new species.)

This little shell differs from *Obolus anceps* Walcott, to which it appears to be most nearly related, by its more nearly circular dorsal valve and its strong, concentrically ridged surface. Its surface is formed by elevated, rounded, concentric ridges that are somewhat irregular. Very fine concentric striæ occur both on the ridges and on the interspaces between.

FORMATION AND LOCALITY.—**Upper Cambrian:** (61) Limestone in the Dunderberg shale [Walcott, 1908f, p. 184] a little south of the Hamburg mine, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

(14b) Limestone on Cold Creek at north end of gorge opposite the north end of Sponge Mountain, 2 miles (3.2 km.) south of the San Saba County line, in Llano County, Texas.

Middle Cambrian: (58) Shaly limestones in the upper beds of Secret Canyon shale, east side of New York and Secret canyons, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

OBOLUS OBSCURUS Walcott.

Plate XI, figures 9, 9a-d.

Obolus obscurus WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 326. (Described and discussed essentially as in the first two paragraphs below as a new species.)

A large dorsal valve of this species has a length of 9 mm., width 7 mm. The shell is strong and marked on its inner layers by radiating and concentric striæ; the outer surface has numerous fine, elevated, slightly irregular, concentric striæ that, with a strong lens, give it a roughened appearance.

An interior of a dorsal valve shows a well-developed area, the greater portion of which is taken by the broad pedicle groove; a deep umbonal cavity with a narrow median septum and obscure main vascular sinuses on the outer margins of the cavity. Outside the sinuses, on the posterolateral slope, relatively large muscle scars are indicated.

Since the publication of the original description (the greater part of which is copied in the two preceding paragraphs), better specimens referred to this species were received from the Middle Cambrian of Shansi. These illustrate the form and convexity of the ventral valve and show it to be similar to that of *Obolus chinensis* (Walcott). The concentric ridges are more nearly perfect than those on the fragments associated with the specimens from Shantung. The concentric striæ or ridges are elevated, rounded, with sharp depressions between them;

the ridges are little more than elevated striæ at the aperture, becoming gradually coarser over the central and anterior portions of the valve, where there are from five to seven ridges in a distance of 1 mm.; toward the apex there are more than double the number in the same distance.

Obolus obscurus has a larger and more rounded shell than *O. chinensis* and is also distinguished by the strong, concentrically striated surface, which resembles that of *Micromitra (Paterina) labradorica orientalis* (Walcott), from which it differs in the form of the shell. It differs from *Obolus (Acritis) antiquissimus* (Eichwald) (Pl. XIII) in having the concentric striæ or ridges more regular and very rarely bifurcating. *Obolus (Acritis?) rugatus* Walcott (Pl. XIII) has much stronger concentric ridges. The surface of *O. nundina* Walcott (Pl. XI) is marked by irregularly spaced, rounded, concentric ridges, with rounded depressions between them, instead of the V-shaped depressions and regularly spaced ridges of *O. obscurus*. *Obolus obscurus* has a large strong shell of the general type of *Obolus rhea* Walcott (Pl. IX) of the Middle and Upper Cambrian of Wisconsin.

The material upon which this species was based [Walcott, 1905a, p. 326] was more or less fragmentary, and the specific name was chosen because of the obscure relations of the species.

FORMATION AND LOCALITY.—Middle Cambrian: (C63) Sandy shale near the base of the Külung group [Blackwelder, 1907a, p. 37 (3d paragraph), and fig. 8a (bed 32), p. 29], 3.5 miles (5.6 km.) southwest of Yenchuang, Sintai district, Shantung; and (C75) limestone near the base of the Kichou formation [Willis and Blackwelder, 1907, p. 143], 4.5 miles (7.2 km.) south of Wutaihen, Shansi; both in China.

OBOLUS? PALLIATUS Barrande.

Plate XV, figure 5.

Obolus? palliatus BARRANDE (in part), 1868, Faune silurienne des environs de Hof, en Bavière, pp. 104-105, fig. 65 (not fig. 64, referred in this monograph to *Obolus? bavaricus*). (Described and discussed in French as a new species. Fig. 65 is copied in this monograph, Pl. XV, fig. 5.)

Obolus? palliatus BARRANDE (in part), 1868, Neues Jahrb. für Mineralogie for 1868, p. 693, unnumbered plate, fig. 65 (not fig. 64, referred in this monograph to *Obolus? bavaricus*). (Text and figures copied from preceding reference.)

This shell is described from the external characters, and on this account was referred provisionally to the genus *Obolus*. The author states that the form is transverse, beak obtuse, and the convexity of the shell as preserved is greatest near the beak. The substance of the shell appears to be like that of the associated *Lingula*. It is ornamented with fine concentric striæ, which tend to group themselves into bands on some specimens. On Barrande's figure radiating striæ are shown, but are not mentioned in the text. Two specimens have a length of 13 mm., with their widths respectively 16 and 18 mm.

FORMATION AND LOCALITY.—Passage beds between the Upper Cambrian and the Ordovician: (303c [Barrande, 1868a, p. 105]) Suburbs of Hof, Bavaria, Germany.

OBOLUS PANDEMIA Walcott.

Plate IX, figures 3, 3a-d.

Obolus pandemia WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 388. (Characterized as below as a new species.)

The external form of this species is much like that of *O. matinalis* (Hall) (Pl. VIII). It differs mainly in the characters of the interiors of the valves. In the ventral valve the central ridge is elevated so as to be the most pronounced feature. It not only fills up the space usually occupied by the heart-shaped cavity, but rises much above the interior surface of the shell. The trapezoidal areas (c) and the depressions occupied by the main vascular sinuses are seen only with difficulty. The essential characters of the species are shown by figures on Plate IX.

FORMATION AND LOCALITY.—Middle Cambrian: (10a) Sandy layers of the Rome formation, in west railroad cut through Shooks Gap, in Bays Mountains, 10 miles (16.1 km.) southeast of Knoxville [Keith, 1895, areal geology sheet], Knox County, Tennessee.

OBOLUS PANDERI Mickwitz.

Obolus panderi MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 149-151, Pl. II, figs. 13a-d. (Described and discussed in German as a new species.)

According to Mickwitz, two fragments of this species have been found. These fragments indicate that the shell was one of the largest species from the *Obolus* sandstone, being nearly twice as large as the nearly related *O. triangularis* Mickwitz. He separates it from the latter species on account of its size, "the pronounced pentagonal angular central groove, and the remarkable combination of the corneous projection with the ridges of the main vascular canals, and the somewhat less convexity of the ventral valve."

Mickwitz states that this species is very rare. He gives a most detailed account of it, to which the student is referred.

The specific name was given in honor of C. H. Pander.

FORMATION AND LOCALITY.—Upper Cambrian: (395 [Mickwitz, 1896, p. 151]) *Obolus* sandstone at Joa, near Jegeleht, 12 miles (19.3 km.) east of Reval, Government of Esthonia, Russia.

OBOLUS PARVUS Walcott.

Text figures 37A-B.

Obolus parvus WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 61-62, Pl. VII, figs. 10 and 10a. (Described and discussed as a new species. Figs. 10 and 10a are copied in this monograph as figs. 37A and 37B.)

Shell small, moderately convex, nearly semicircular in outline. Ventral valve a little longer than wide and with the umbo curving gently to the minute marginal beak. Dorsal valve a little wider than long and with apex marginal. Surface marked by minute concentric striae of growth and an exceedingly fine network of irregular lines that, with a lens magnifying 20 diameters, give it the appearance of the surface of *Lingulella (Lingulepis) longinervis* (Matthew) (Pl. XLIV, fig. 1p). Nothing is known of the interior of the valves.

FIGURE 37.—*Obolus parvus* Walcott. A, exterior of a ventral valve, the typespecimen (U. S. Nat. Mus. Cat. No. 51400a). B, exterior of a dorsal valve (U. S. Nat. Mus. Cat. No. 51400b).

Figures 37A and 37B are copied from Walcott [1908d, Pl. VII, figs. 10 and 10a]. The specimens are from Locality 35c, Lower Cambrian shale, on Mount Bosworth, British Columbia.

The average diameter of the valves is from 1.5 to 2 mm., with the ventral valve a little longer than wide and the dorsal valve slightly transverse in outline.

In outline the shell approaches most nearly to *Obolus rotundatus* (Walcott) (Pl. XX, figs. 2, 2a-e) of the Middle and Upper Cambrian. It differs in having a more rounded posterior outline in the ventral valve and in its more transverse dorsal valve. *Obolus pheres* Walcott (Pl. XI, figs. 6, 6a-b) of the Upper Cambrian is a very small shell, but it is thicker and also more elongate than *O. parvus*. In form it resembles

Obolus minimus Walcott, from China (Pl. XI, figs. 8 and 8a), but it differs in having a less elongate ventral valve and in its peculiar surface.

FORMATION AND LOCALITY.—Lower Cambrian: (35c) Drift blocks of siliceous shale supposed to have come from the Mount Whyte formation [Walcott, 1908f, p. 214], found on the south slope of Mount Bosworth, about 500 feet (152 m.) northwest of the Canadian Pacific Railway track between Stephen and Hector, eastern British Columbia.

(35e) About 270 feet (82.3 m.) below the Middle Cambrian, in a greenish siliceous shale correlated with No. 3 of the Mount Whyte formation on Mount Bosworth [Walcott, 1908f, p. 214], in the amphitheater between Popes Peak and Mount Whyte, about 3 miles (4.8 km.) northwest of Lake Louise, southwest of Laggan, on the Canadian Pacific Railway; and (58t) sandy shale about 150 feet (45.7 m.) below the Middle Cambrian, just below the big cliff on the east shoulder of Castle Mountain, north of the Canadian Pacific Railway; both in Alberta, Canada.

OBOLUS PHERES Walcott.

Plate XI, figures 6, 6a-b.

Obolus pheres WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 328. (Characterized as below as a new species.)

This is one of the smallest of the *Obolus* species known to me, as it does not average 2 mm. in diameter. It recalls at first sight *Lingulella winona convexa* (Walcott); but it differs in having a thick lamellated shell and in being more rounded on the cardinal angles. The exterior

surface is marked by concentric lines of growth. The shell is built up of thin layers or lamellæ, those toward the front and sides being arranged obliquely to the surface, as in all of the thick-shelled species of *Obolus*.

FORMATION AND LOCALITY.—**Upper Cambrian:** (10v) Shales in the "St. Croix sandstone," at Fox Glen, about 8 miles (12.8 km.) east of Baraboo, Baraboo quadrangle (U. S. Geol. Survey), Sauk County, Wisconsin.

OBOLUS PRINDLEI (Walcott).

Plate XXVII, figures 3, 3a-e.

Obolus (Lingulella) prindlei WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 412. (Characterized and discussed essentially as below as a new species.)

This species was at first considered to be identical with *Lingulella granvillensis* Walcott (Pl. XXII). The study of a new lot of well-preserved specimens shows that it differs from *granvillensis* in being less elongate, more ovate in outline, and marked upon the interior by a very finely granulated surface; in the cast the papillæ and the fine depressions between them appear to be arranged in transverse undulating lines. The transverse lines of growth on the area of the ventral valve, as seen in the cast, are peculiar in having an imbricating or lamellose-like arrangement. The areas of both valves are rather large for so small a species. The average length of the ventral valve is 3.5 mm. to 4 mm., and the width is 3.25 mm. The dorsal valve is a little shorter than the ventral.

Obolus prindlei belongs to a group of small shells (Pls. XXIX to XXXI) that is represented by *Lingulella ferruginea* Salter, *Obolus rotundatus* (Walcott), *Lingulella desiderata* (Walcott), *Obolus chinensis* (Walcott), *Lingulella damesi* (Walcott), and *L. granvillensis* Walcott. These forms are among the earliest specimens of the genus and range through to the Ordovician fauna. *Lingulella granvillensis* and *Obolus prindlei* occur in the upper limit of the *Olenellus* fauna of eastern New York and western Vermont, and *Obolus rotundatus* and *Lingulella manticula* (White) are found at the base of the Ordovician fauna.

The specific name is given in recognition of the effective work of Mr. L. M. Prindle, who, as assistant to Prof. T. Nelson Dale, collected the first specimens of the species.

FORMATION AND LOCALITY.—**Lower Cambrian:** (29) Limestone just above the bridge at the Stockport paper mill on Kinderhook Creek, Columbia County; (35) limestones 1.5 miles (2.4 km.) north of Bald Mountain and 3.5 miles (5.6 km.) north-northwest of Greenwich, Schuylerville quadrangle (U. S. Geol. Survey), Washington County; (45b) limestone near the roadside about 1,200 feet (366 m.) east of Bristol's house, near Low Hampton, about 5 miles (8 km.) east-northeast of Whitehall, Whitehall quadrangle (U. S. Geol. Survey), Washington County; (36b) limestones near school-house No. 12, near Greenwich, Cambridge quadrangle (U. S. Geol. Survey), Washington County; (38a) limestone 2 miles (3.2 km.) south of North Granville, on the road which turns south from the road running between that village and Truthville, 4 miles (6.4 km.) west-northwest of Granville, Fort Ann quadrangle (U. S. Geol. Survey), Washington County; (72) limestone 5 miles (8 km.) east of Albany, Rensselaer County; (2b) limestone just north of Beman Park, in the northeastern part of the city of Troy, Rensselaer County; (338k) limestone 2.5 miles (4 km.) southwest of Wynantskill, Rensselaer County; and (72a) limestone 1 mile (1.6 km.) southwest of Wynantskill, Rensselaer County; all in New York.

Specimens that are compared with *Obolus prindlei* occur at the following locality:

Lower Cambrian: (25a) Limestone on the Hall (Donaldson's) farm, 2 miles (3.2 km.) east of Swanton, Franklin County, Vermont.

OBOLUS REFULGENS Matthew.

Plate IX, figures 2, 2a-d.

Obolus refulgens MATTHEW, 1892, Trans. Roy. Soc. Canada, vol. 9, sec. 4, No. 5, pp. 44-45, Pl. XII, figs. 6a-d. (Described and discussed as a new species. The specimens represented by figs. 6d (ventral) and 6d (dorsal) are redrawn in this monograph, Pl. IX, figs. 2 and 2a, respectively.)

Obolus ? refulgens MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Petersbourg, 8th ser., vol. 4, No. 2, pp. 23-24. (Discussed in German.)

Obolus refulgens MATTHEW, 1902, Trans. Roy. Soc. Canada, 2d ser., vol. 8, sec. 4, No. 3, p. 96, plate opposite p. 112, figs. 11a-b. (Discussed.)

Obolus (Monobolina) refulgens MATTHEW, 1902, idem, p. 98. (Changes generic reference.)

Monobolina refulgens MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, pp. 210-213, Pl. XVI, figs. 2a-b, Pl. XI, figs. 4a-b. (Copies the original description, Matthew, 1892, pp. 44-45, and describes and discusses species. Pl. XI, figs. 4a-b, are copied from Matthew, 1892, Pl. XII, figs. 6d (ventral) and 6d (dorsal); Pl. XVI, figs. 2a-b, are copied from Matthew, 1902b, plate opposite p. 112, figs. 11a-b.)

General form transversely ovate, the dorsal valve being slightly more rounded at the beak than the ventral. Valves rather strongly convex, as seen in a single specimen of an uncompressed dorsal valve; most of the shells are flattened in the shale. Surface of shell marked by concentric lines of growth and very fine, irregular striæ that inosculate so as to produce a surface much resembling that of *Obolus fragilis* (Walcott), *Lingulella bellula* (Walcott), *Obolus (Westonia) cilla* (Hall and Whitfield), and other forms. The shell is not preserved on any of the specimens in the collection. A ventral valve 6.25 millimeters in length has a width of 6.5 millimeters; a larger dorsal valve 8 mm. in length has a width of 9 mm.

The cast of the interior of the valves shows a clearly defined rather strong area on each valve. The only muscle scars clearly defined are the central scars of the dorsal valve.

Observations.—This species has the general form of *Obolus mickwitzii* Walcott (Pl. X) but in the absence of good specimens detailed comparisons are of little value.

Matthew [1902b, p. 98] includes *Obolus refulgens* in the subgenus *Monobolina* Salter [1866b, p. 334] on account of the close approximation of the "anterior adductor scars" of the dorsal valve.

The illustrations by Davidson [1866, Pl. IV, figs. 20-27] of *Monobolina plumbea* (Salter) indicate a platform of the type of that found in *Elkania* (Pl. LI, figs. 1, 1a, and 4b), and as *Monobolina plumbea* is a Lower Ordovician species it may be that the latter is a descendant of *Elkania* of the Cambrian. It is certainly not an *Obolus*.

FORMATION AND LOCALITY.—Upper Cambrian: (308 [Matthew, 1892, p. 45]) Shales of Division C3c of Matthew [1892, p. 43], at Navy Island, St. John Harbor, New Brunswick.

(307 [Matthew, 1903, p. 213]) Shales of Division C3c of Matthew [1901a, p. 276], on McLeod Brook (=Barachois River); and (372e [Matthew, 1903, p. 50]) shales on McMullins Brook, near McLeod Brook; both in Cape Breton, Nova Scotia.

OBOLUS RHEA Walcott.

Plate IX, figures 1, 1a-c.

Obolus rhea WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, pp. 387-388. (Described and discussed as below as a new species.)

General form elongate ovate, with the ventral valve subacuminate, and the dorsal valve elongate ovate in outline. Outer surface unknown, as all of the shells referred to this species are more or less exfoliated; the surface of the inner layers shows numerous, rather broad, radiating striæ, and concentric lines of growth. The shell appears to have been formed of a thin outer layer and several inner layers or lamellæ arranged in the same manner as in *Obolus matinalis* (Hall). A ventral valve 8 mm. in length has a width of 6 mm.; a shorter, broader valve is 6.5 mm. long and 5.5 mm. wide. The two dorsal valves referred to this species are larger than the ventral valves; one 9.25 mm. long has a width of 6.75 mm. and another 9.25 mm. long has a width of 7.25 mm.

Casts of the interior of the ventral valve show a rather short area that is not clearly defined in any of the specimens. The cast of the pedicle groove is narrow and merges into the cast of the groove extending forward to the visceral area; the area is also marked by flexure lines and transverse striæ of growth. The area of the dorsal valve is short in the one specimen showing it. The cast of the visceral cavity on a ventral valve is clearly defined by a rather narrow ridge that is expanded anteriorly in what may represent the heart-shaped cavity (v) (Pl. IX, figs. 1, 1a). The parietal scar passes around in front of the visceral cavity and then a little backward to the main vascular sinuses. No traces of a median septum have been seen in either valve.

The only traces of muscle scars observed are some irregular markings in the trapezoidal area (c), in which the central, middle lateral, and outside lateral scars occur in the ventral valve.

Observations.—This somewhat peculiar species is associated with *Obolus namouna* Walcott, *Dicellomus politus* (Hall), and *Obolus matinalis* (Hall). The dorsal valves are clearly distinct from any described form, approaching in some respects the elongate dorsal valve of *Lingulella* (*Lingulepis*) *acuminata* (Conrad) (Pls. XL to XLII), differing, however, in being narrow and more elongate; the ventral valves appear to be broader in proportion than the dorsal valve and approach *O. matinalis* (Hall) (Pl. VIII) in outline but are more elongate.

FORMATION AND LOCALITY.—Upper Cambrian: (98) “St. Croix sandstone” at Eau Claire, Eau Claire County, Wisconsin.

Middle Cambrian: (84) “St. Croix sandstone” at Dresbach, opposite the mouth of Black River, Winona County, Minnesota.

OBOLUS? ROKITZANENSIS Barrande.

Plate XII, figure 6.

Obolus? rokitzanensis BARRANDE, 1879, *Système silurien du centre de la Bohême*, vol. 5, Pl. CXXVI, fig. II: 5. (No text reference. Fig. 5A is copied in this monograph, Pl. XII, fig. 6.)

Barrande gives only one illustration of this species. It recalls to mind those forms of *Obolus* which preserve the radial striation on the interior surface. The configuration of the visceral area also suggests that of the ventral valve of *Obolus*. The illustration is introduced in order that the student may have before him a representation of all of the *Obolus*-like shells known to me. Figure 5 of Barrande [1879b, Pl. CXXVI] should be compared with the ventral valve of *Obolus complexus* Barrande (Pl. XII, fig. 3, of this monograph), and for the radial striation with Plate XII, figure 3b.

The specific name is derived from Rokitzan, the type locality.

FORMATION AND LOCALITY.—Lower Ordovician: (303b [Barrande, 1879b, Pl. CXXVI]) Étage d1 in the environs of Rokitzan, Bohemia, Austria-Hungary.

OBOLUS ROTUNDATUS (Walcott).

Plate XX, figures 2, 2a-e.

Obolus (*Lingulella*) *rotundatus* WALCOTT, 1898, *Proc. U. S. Nat. Mus.*, vol. 21, p. 415. (Characterized as a new species; see first paragraph below for copy.)

Obolus (*Lingulella*) *desideratus* WALCOTT, 1899, *Mon. U. S. Geol. Survey*, vol. 32, pt. 2, pp. 445-446, Pl. LX, fig. 2a (not fig. 2, referred to *Lingulella desiderata*). (Described and discussed. The specimen represented by figure 2a is redrawn in this monograph, Pl. XX, fig. 2e.)

This small species is associated with *Lingulella manticula* (White). It differs from it in its nearly circular form and more strongly pitted or punctate interior of the valves. A cast of the interior of a dorsal valve shows a well-defined area, the cast of the median ridge and septum, and the central muscle scars. The ventral valve has a length of 3.5 mm., width 3 mm.; dorsal valve, length 3 mm., width 3 mm.

The shells represented by Plate XX, figures 2 and 2a, are associated in the same hand specimens of limestone with *Lingulella manticula*. The specimens represented by Plate XX, figures 2b, 2c, and 2d, are from the Upper Cambrian beds of the Gallatin Valley, Montana, but so far as can be determined from the material at hand for comparison they appear to represent the same species.

FORMATION AND LOCALITY.—Lower Ordovician: (313d) *Limestone at Schellbourne, Schell Creek Range, White Pine County, Nevada.*

Upper Cambrian: (160a) Sandstone west of Bear Creek, south of the Gallatin Valley, southwest of Bozeman, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County, Montana.

(30q) Limestones about 2,300 feet (701 m.) above the Cambrian quartzites, on pipe line above limekiln, in Ogden Canyon, 1 mile (1.6 km.) above its mouth, east of Ogden, Weber County; (34i) shales about 1 mile (1.6 km.) northeast of Sand Pass, at the south end of the Fish Spring Range, Juab County; (33d) thin-bedded blue limestone at the base of the first high point southwest of the J. J. Thomas ranch, on the east side of the Fish Spring Range, Juab County; (30y) about 1,400 feet (426.7 m.) above the Middle Cambrian and 1,900 feet (579.1 m.) below the top of the Upper Cambrian in the supposed metamorphosed equivalent of the shales forming 1b of the Orr formation [Walcott, 1908f, p. 176], above the granite contact on top of the ridge north of Notch Peak [Walcott, 1908f, Pls. XIII and XIV], House Range, Millard County; and (34r) limestones 1.5 miles (2.4 km.) northwest of Wahwah Spring, about halfway up the section to the north of the road at Cane Pass, Wahwah Mountains, Beaver County; all in Utah.

(80) Limestone on the slope of the ridge where the range swings around to the northwest, 2 miles (3.2 km.) north of Aurum, Schell Creek Range, White Pine County, Nevada.

(96) Limestone near the ford on the Cedartown road, 1.5 miles (2.4 km.) south of Rome, Floyd County, Georgia.

Middle Cambrian: (159) Limestones north of West Gallatin (Gallatin River, Gallatin County, Montana.

(302b) Limestones near Crowfoot Ridge, Gallatin quadrangle (U. S. Geol. Survey), Yellowstone National Park, Wyoming.

(34n) Shales about 100 feet (30.5 m.) above the Tintic quartzite [G. O. Smith, 1900, p. 1] near the summit of the ridge between Mammoth and Eureka, Tintic special quadrangle (U. S. Geol. Survey), Juab County, Utah.

(11o) About 2,750 feet (838.2 m.) above the Lower Cambrian and 1,650 feet (502.9 m.) below the Upper Cambrian, at the base of the limestone forming 1a of the Marjum limestone [Walcott, 1908f, p. 179], about 4 miles (6.4 km.) southeast of Antelope Springs in the spur at the junction of the Deseret and Swasey Spring roads [Walcott, 1908f, Pl. XIII], House Range, Millard County; (11x) about 2,200 feet (670.6 m.) above the Lower Cambrian and 2,200 feet (670.6 m.) below the Upper Cambrian in the limestones forming 1d of the Marjum limestone [Walcott, 1908f, p. 180], 2.5 miles (4 km.) east of Antelope Springs, in ridge east of Wheeler Amphitheater [Walcott, 1908f, Pls. XIII and XV], House Range, Millard County; all in Utah.

(7i) Limestone just west of the summit on the road east of Schellbourne, Schell Creek Range, White Pine County; and (7j) limestones at the north end of the Quinn Canyon Range, 1 mile (1.6 km.) northwest of Italian Ranch foothills, Nye County; both in Nevada.

Specimens that are somewhat doubtfully referred to this species occur at the following locality:

Upper Cambrian: (8p) Limestone halfway up the canyon east of McGill's ranch, on the west side of the Schell Creek Range, 14 miles (22.5 km.) northeast of Ely, White Pine County, Nevada.

OBOLUS SCHMALENSEEI (Walcott).

Plate XXX, figures 19, 19a-e.

Obolus (Lingulella) schmalensei WALCOTT, 1902, Proc. U. S. Nat. Mus., vol. 25, p. 605. (Characterized as below as a new species.)

This is the European representative of the American *Obolus rotundatus* (Walcott) (Pl. XX). Its outline is slightly elongate to subcircular. When the shell is exfoliated, the cast indicates that it was strong over the visceral area and thin toward the margins. The characteristic features are well shown in the drawings.

The specific name is given in honor of Mr. Schmalensee, who collected the material for me.

FORMATION AND LOCALITY.—**Middle Cambrian:** (8w) Limestones of *Paradoxides forchhammeri* zone, at Andrarum, 20 miles (32 km.) northwest of Simrishamn, Province of Christianstad, Sweden.

(16h) Limestones of the *Paradoxides forchhammeri* zone, at Borregaard; and (16i) limestones of the *Conocoryphe exculans* zone, at Borregaard; both on Bornholm Island, Denmark.

OBOLUS SCHMIDTI Mickwitz.

Plate XV, figures 11a-c.

Obolus schmidti MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Petersbourg, 8th ser., vol. 4, No. 2, pp. 152-154, Pl. II, figs. 14a-c. (Described and discussed in German as a new species; see below for translation of the diagnosis. Figs. 14a-c are copied in this monograph, Pl. XV, figs. 11a-c, respectively.)

The original description by Mickwitz follows:

Shells large, moderately arched; outline broad, egg-shaped; posterior borders of shell convex, not winged; beak of the large shell scarcely prolonged. Surface of shell faintly polished. Growth lamellæ marked by deep, regular, roughly cut concentric furrows. Concentric striæ fine, irregular, mingled. Radial striæ perceptible as indistinct traces. Area of large shell very small, peduncular groove pit-shaped. Thickening of posterior part of shell falling away in two terraces to middle of shell. First terrace is steep at the broadest place of the heart-shaped groove, the second flat in front of the point of the latter. Posterior part of the thickening in the form of two club-shaped swellings, which, separated at their posterior thick parts by a deep furrow in the prolongation of the peduncular groove, pass over with their anterior ends into the swellings of the principal vessel furrows. Splanchnocœle of the large shell strikingly shortened. Secondary, inwardly diverging traces of the vessels rectilinear, not ramified.

Observations.—Mickwitz states that, in addition to the concentric striæ described and very faint traces of radial striæ, there are over the entire rather rough surface of the shell scattered, irregular, flat grooves, whose radial position is unmistakable. He also calls attention to the

peculiar interior configuration as described and shown in the illustrations. This species is stated to be very rare and restricted to the *Obolus* sandstone.

The specific name was given in honor of Dr. Fr. Schmidt.

FORMATION AND LOCALITY.—Upper Cambrian: (395 [Mickwitz, 1896, p. 153]) *Obolus* sandstone at Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval, Government of Esthonia, Russia.

OBOLUS SELWYNI (Matthew).

Plate XXXVI, figures 1, 1a-h, 2, 2a-b; Plate XXXVII, figures 1, 1a-f.

Lingulella selwyni MATTHEW, 1895, Trans. Roy. Soc. Canada for 1895, 2d ser., vol. 1, sec. 4, No. 13, pp. 255-256, Pl. I, figs. 1a-b. (Described and discussed as a new species. The specimen represented by fig. 1b is redrawn in this monograph, Pl. XXXVII, fig. 1c.)

Obolus æquiputeis MATTHEW, 1902, idem, 2d ser., vol. 8, sec. 4, No. 3, p. 94, Pl. I, figs. 4a-e. (Characterized. The specimens represented by figures 4b and 4d are redrawn in this monograph, Pl. XXXVI, figs. 2 and 2a, respectively.)

Lingulella selwyni MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, pp. 62-63. (Notes on orientation of shells.)

Lingulella selwyni MATTHEW, 1903, idem, pp. 116-123, figures on p. 117, and Pl. VII, figs. 1a-c. (Described and discussed. The original reference, Matthew, 1895, pp. 255-256, is copied on pp. 120 and 121. The figures given on p. 117 are diagrammatic drawings based on the specimens figured by Matthew, 1895, Pl. I, figs. 1a and 1b. Matthew's original drawings are, however, also copied in this reference, Matthew, 1903, Pl. VII, figs. 1a and 1b. Pl. XXXVII, fig. 1c, of this monograph represents the specimen upon which Matthew based the diagrammatic figures given in the right-hand figure on p. 117 and that given in Pl. VII, fig. 1b. Pl. XXXVI, figs. 1 and 1c, of this monograph represent the specimens on which Matthew based the diagrammatic figures given in the left-hand figure on p. 117 and that given in Pl. VII, figs. 1a and 1c.)

Obolus æquiputeis MATTHEW, 1903, idem, p. 139, Pl. VIII, figs. 2a-e. (Described as a new species, but it is not the first reference to the species; see above. The marginal reference gives the species as *Obolus (Eoobolus) æquiputeis*. Figs. 2a-e are copied from Matthew, 1902, Pl. I, figs. 4a-e.)

General form subovate, broadly rounded in front. Ventral valve subacuminate and dorsal valve broadly rounded at the beak. Surface of the shell marked by very fine, concentric striæ and lines of growth and indistinct very narrow undulations of the shell radiating from the beak. When the thin exterior shell is exfoliated fine radiating lines are seen, and the inner surface (outside of the visceral areas) shows radiating lines toward the anterior margin and irregularly distributed punctæ. The shell is of rather more than medium thickness. It is built up of a thin outer layer and several inner layers, very much as the shell of *Lingulella acutangula* (Roemer) (Pl. XVII, figs. 1m, 1n, and 1o).

A large, slightly distorted ventral valve has a length of 14 mm.; width, 11 mm. The original proportion of length and width of this specimen was probably 14 to 12. The dorsal valve was probably of equal length and width.

The area of the ventral valve is more or less distorted in all the specimens; its character is best shown in Plate XXXVII, figure 1b; and the area of the dorsal valve in Plate XXXVII, figure 1e. The pedicle furrow is strong and well defined (Pl. XXXVII, fig. 1b).

The cast of the interior of the ventral valve shows the visceral cavity and the heart-shaped pit (x) (Pl. XXXVII, fig. 1d) so characteristic of *Obolus*. There are no traces of a median septum in the ventral valve; in the dorsal valve it is a sharp, narrow ridge (Pl. XXXVI, figs. 1e-g).

The muscle scars of the valves are well shown in casts of the interior. The umbonal scar of the dorsal valve is elongate (Pl. XXXVII, figs. 1c and 1f, and Pl. XXXVI, fig. 1e). I have not observed it in the ventral valve. The scars of the central muscles (h) are distinct in the dorsal valve (Pl. XXXVII, fig. 1c), but on the ventral valve they are merged with the middle laterals in the trapezoidal area (c) (fig. 1d). The outside laterals (l) are preserved in interiors of the ventral valve (Pl. XXXVI, figs. 1d and 1e) and the dorsal valve (Pl. XXXVI, fig. 1e). The middle laterals (k) are shown on the dorsal valve (Pl. XXXVI, fig. 1e), but have not been seen on the ventral valve. The anterior laterals are shown for the dorsal valve at (j) (fig. 1c). The transmedian scars (i) are preserved on casts of the dorsal valve (Pl. XXXVII, figs. 1c, 1e, and 1f) and the ventral valve (Pl. XXXVI, fig. 1a).

The parietal scar is clearly shown in front of the visceral cavity of the ventral valve, between the main vascular sinuses (ps) (Pl. XXXVII, fig. 1d), but it has not been traced beyond the main sinus. On the dorsal valve its course may be followed from the median line in front of the anterior lateral muscle scars (j), back beyond the central scars (h), to a point where it curves outward (ps) (Pl. XXXVII, fig. 1c).

Observations.—Matthew sent me the types of this species for study and illustration. From the first lot sent in 1900 the figures on Plate XXXVII were made. A second lot sent in 1903 gave the fine illustrations on Plate XXXVI. The two figures in his paper (1895b, Pl. I) of the ventral and dorsal valve are essentially diagrammatic, combining as they do the characters seen in a number of specimens. I have illustrated several of the specimens that appear to me to give a fair presentation of the characters.

As stated by Matthew [1895b, p. 256] the plan of the muscular scars of this species is very nearly that of *Obolus apollinis quenstedti* (Mickwitz). It may also be compared with the arrangement of the scars of *Lingulella acutangula* (Roemer). Further reference to *O. selwyni* will be found under the discussion of *Obolus* and *Lingulella* (p. 377). In a general way comparison may be made between *Obolus selwyni* and *Lingulella acutangula*; specifically there are strong variations between them.

Obolus æquiputeis Matthew appears to be in all respects identical with *O. selwyni*. To illustrate the identity of the two species photographs were made of the types of *O. æquiputeis* (Pl. XXXVI, figs. 2, 2a-b). The dorsal interiors have both been distorted. In figure 2b the distortion is from transverse compression; in figure 2c from longitudinal compression. The specimen represented by the latter is associated with *Obolus selwyni*. The specimens represented by Plate XXXVI, figures 2a and 2b, are casts in a matrix that preserves the interiors very clearly. Plate XXXVI, figure 2c, and all other illustrated specimens of this species, are from a matrix in which the shell is compressed so as to obscure the interior markings.

The calcareous sandstones in which this species occurs were referred to the Ordovician by Matthew [1895b, p. 255], but in his review of the Cape Breton Cambrian faunas [1903, p. 123] he assigns it to Division E2a? of his lower Etcheminian.

The specific name was given in honor of Dr. A. R. C. Selwyn.

FORMATION AND LOCALITY.—Middle Cambrian: (307d [Matthew, 1903, p. 123]) Sandy limestone of Division E2a? of Matthew's [1903, p. 19] Etcheminian, on Young (McFees) Point near George River Station, on the Intercolonial Railway, eastern Cape Breton, Nova Scotia.

OBOLUS SEPTALIS (Walcott).

Plate XXIII, figure 3d; Plate XXXIV, figures 2, 2a.

Obolus (Lingulella) septalis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 331. (Characterized as below as a new species.)

Obolus mcconnelli WALCOTT (in part), 1908, Canadian Alpine Journal, vol. 1, No. 2, p. 244, Pl. I, fig. 2a (not fig. 2, which represents a specimen of *Obolus mcconnelli*). (No text reference. Fig. 2a is copied in this monograph, Pl. XXIII, fig. 3d.)

The dorsal valve is all that is known of this little shell. There are two specimens in the collections of the United States National Museum and three in the collection of Bryon E. Walker, of Toronto, Canada.

The general form of the valves is much like that of *Obolus rotundatus* (Walcott) (Pl. XX). It is distinguished from the latter and other described species by the strong median ridge and septum of the dorsal valve. The outer surface is marked by concentric striæ and lines of growth and very fine irregular concentric striæ that give a minutely rough surface.

This form owes its specific name to the presence of a septum in the dorsal valve.

FORMATION AND LOCALITY.—Middle Cambrian: (14s) About 2,300 feet (701 m.) above the Lower Cambrian and 2,700 feet (823 m.) below the Upper Cambrian in the *Ogygopsis* zone of the Stephen formation [Walcott, 1908f, p. 210], at the "fossil bed" on the northwest slope of Mount Stephen, above Field on the Canadian Pacific Railway, British Columbia, Canada.

OBOLUS SHANSIENSIS Walcott.

Plate XI, figures 7, 7a-c.

Obolus shensiensis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 327. (Described and discussed as below as a new species, the spelling *shensiensis* being in error because the type specimens came from a locality in the Province of Shansi, not Shensi, although the species occurs in that province.)

General form ovate, with the ventral valve broadly subacuminate and dorsal valve obtusely rounded. Valves moderately convex in the specimens embedded in a fine-grained, dark limestone. Surface marked by fine, sharp, concentric striæ and traces of irregular, obscurely defined, low, radiating ridges; the interior layers show fine radiating striæ and concentric lines; the shell is strong and built up of numerous lamellæ oblique to the outer surface. The largest ventral valve has a length of 9 mm., width 7 mm. Nothing is known of the interior of the valves.

The form, surface markings, and shell structure are much like those of *Obolus matinalis* (Hall) (Pl. VIII) and *O. tetonensis* Walcott (Pl. IX). In outline *O. shansiensis* is more elongate than *O. matinalis* and less so than *O. tetonensis*.

This form owes its specific name to the occurrence of the type specimen in the Province of Shansi, China.

FORMATION AND LOCALITY.—Middle Cambrian: (C37) Upper part of the Kichou limestone in dense black limestone nodules in green-gray shales 10 feet below the base of the cliff limestone [Willis and Blackwelder, 1907, p. 146], 8 miles (12.8 km.) south of Tinghianghien, Shansi; (C32) A fine-grained bluish-black limestone boulder believed to have come from the lower part of the Kisinling limestone [Blackwelder, 1907b, p. 272], collected in river drift 1 mile (1.6 km.) south of Chonpinghien, on Nankiang River, southern Shensi; and (C71)^a massive cliff-forming limestone in the central portion of the Kichou formation [Willis and Blackwelder, 1907, pp. 139 and 145 (2d list of fossils)], 4 miles (6.4 km.) southwest of Tungyu, Shansi; all in China.

OBOLUS SINOË (Walcott).

Plate XXVI, figures 2, 2a-h.

Obolus (Lingulella) sinoë WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, pp. 416-417. (Described and discussed as below as a new species.)

General form broad ovate, with the ventral valve broadly subacuminate and the dorsal valve broadly ovate. Valves moderately convex, as far as can be determined from the series of shells preserved in the fine-grained sandstone. A ventral valve 5 mm. in length has a width of 4.25 mm. A dorsal valve 4 mm. in length has an equal width.

The traces remaining of the exterior shell show it to have been marked by concentric lines and striæ of growth; when the outer layer is exfoliated radiating striæ cross the lamellæ; a fragment of the inner surface of the shell indicates that there were scattered pits or punctæ and fine radiating striæ; the shell was relatively thick and formed of a thin outer layer and several inner layers or lamellæ, the lamellæ of the anterior portion of the shell being arranged in layers slightly oblique to the outer surface of the shell.

Casts of the interior of the ventral valve show a well-defined area marked by strong flexure lines that occur midway between the lateral margins and the narrow, well-defined pedicle groove; striæ of growth cross the area parallel with its base. The area of the dorsal valve is relatively short and does not extend very far out on the cardinal slopes. The interior markings of the ventral and dorsal valves show imperfectly the main vascular sinuses and visceral area, the central and anterior lateral muscle scars, and a narrow median ridge.

Observations.—This species occurs at the same relative stratigraphic horizon as *Lingulella ino* (Walcott) (Pl. XXVI) and is about the same size. It differs, however, in its more circular form, which is persistent in a large number of shells. In form it more nearly resembles *Obolus rotundatus* (Walcott) (Pl. XX) of the Upper Cambrian. It differs from that in being uniformly

^a This species is somewhat doubtfully identified from this locality.

larger and in having a thicker, stronger shell. Some of the shells in the limestone look very much like *Dicellomus politus* (Hall) (Pl. LII) when they are not compressed.

FORMATION AND LOCALITY.—**Upper Cambrian:** (327) Arenaceous limestone east of Gold Camp, Caballos Mountains, New Mexico.

(302a) Limestone 200 yards (183 m.) north of the southwest corner of sec. 18, T. 28 N., R. 113 W., Uinta County, Wyoming.

(14b) Limestone on Cold Creek at north end of gorge opposite the north end of Sponge Mountain, 2 miles (3.2 km.) south of the San Saba County line, in Llano County; (14c) limestone in Bartlett Hollow, 2 miles (3.2 km.) southeast of the mouth of Falls Creek, Burnet quadrangle (U. S. Geol. Survey), Lampasas County; (67) sandstone on Tatur Hill, 7 miles (11.2 km.) northwest of Burnet, Burnet County; (69) limestone near Honey Creek, Burnet County; (71) limestone in Cold Creek Canyon, Burnet County; (68y) interbedded sandstone and limestone, Packsaddle Mountain, Llano County; and (70) limestone near Morgans Creek, Burnet County; all in Texas.

Middle Cambrian: (302x) Sandstones near the head of Powder River, Bighorn Mountains, Wyoming.

(11j) Basal part of Bonneterre limestone, Mine Lamotte, Madison County, Missouri.

(11a) Sandstone between First and Armstrong creeks, in the southeast corner of the Maynardville quadrangle (U. S. Geol. Survey), Union County, Tennessee.

(92x) Conasauga ("Coosa") shale at Yanceys Bend, Coosa River, southeast of Center, Cherokee County, Alabama.

OBOLUS SMITHI Walcott.

Text figures 38A–C.

Obolus smithi WALCOTT (in part), 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 62–63, Pl. VII, fig. 9a (not fig. 9, which represents a specimen of *Micromitra (Paterina) major*).^a (Described and discussed as below as a new species. Fig. 9a is copied in this monograph as fig. 38B.)

General form broadly ovate, with the ventral valve obtusely acuminate and the dorsal valve subcircular, slightly transverse; convexity apparently moderate, judging from the specimens as they occur slightly flattened out in the calcareous shales.

The shell was relatively strong and formed of a number of thin layers or lamellæ that, toward the outer edge of the valve, were more numerous and gave a scaly appearance to the margins of the old shells.

Surface marked by concentric lines of growth and numerous very fine, slightly

FIGURE 38.—*Obolus smithi* Walcott. A, Exterior of partly exfoliated ventral valve (U. S. Nat. Mus. Cat. No. 51611a). B, Exfoliated dorsal valve, the type specimen (U. S. Nat. Mus. Cat. No. 51611b). C, Partly exfoliated shell showing laminations (U. S. Nat. Mus. Cat. No. 51611c).

Figure 38B is copied from Walcott [1908d, Pl. VII, fig. 9a]. The specimens represented are all from Locality 56c, near Helena, Alabama.

irregular, undulating concentric ridges upon which numerous very minute papillæ occur, giving the surface, under a strong magnifying power, the appearance of being minutely granular.

A ventral valve 6 mm. in length has a width of 6.75 mm. A slightly larger dorsal valve 7.5 mm. in length has a width of 8 mm.

As shown in the cast, the area of the ventral valve is very short and divided by a relatively strongly marked, narrow pedicle furrow, the edges of which were elevated slightly above the general plane of the area. The cast of the interior shows that the visceral area was about two-fifths the length of the valve and that the main vascular sinuses extended rather directly forward from the umbo nearly to the front of the shell, separating very gradually and bounding the interior third of the valve. Nothing has been observed of the muscle scars.

The cast of the dorsal valve shows that it had a very short area that extended well out on the cardinal slopes; that a low central ridge extended a little more than half the length of the shell and was continued by a slight narrow median ridge; the main vascular sinuses extend directly and obliquely forward well toward the front of the shell in about the same relative position as in the ventral valve. The position of the transmedian and anterior lateral muscle

^a See note accompanying the second reference in the synonymy of *Micromitra (Paterina) major* (p. 351) and the note following fig. 25, p. 351.

scars is indicated about halfway between the main vascular sinuses and the posterolateral margin of the valve.

Observations.—This species is characterized by its finely granular surface, short cardinal area, and relatively thick shell. It has the general form of *Obolus lamborni* (Meek) and *Obolus willisi* (Walcott), but it differs from both of these species in having a granulated surface and shorter cardinal area. It appears to be the Lower Cambrian form that is represented in the Middle Cambrian by *Obolus willisi* and in the Upper Cambrian by *Obolus lamborni*.

The specific name is given in honor of Prof. Eugene A. Smith, State geologist of Alabama.

FORMATION AND LOCALITY.—**Lower Cambrian:** (17b) Rome ("Montevallo") formation, 4 miles (6.4 km.) south of Helena; and (56c) Rome ("Montevallo") formation, along road just north of Buck Creek, 1.125 miles (1.8 km.) northeast of Helena; both in Shelby County, Alabama.

OBOLUS TETONENSIS Walcott.

Plate IX, figures 5, 5a–d.

Obolus tetonensis WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 684. (Characterized and discussed as below as a new species.)

Obolus tetonensis WALCOTT, 1905, idem, vol. 28, p. 327. (Copy of preceding reference, the species being given as new and no reference being made to the preceding citation.)

The general form, convexity, and appearance of this species are so much like those of *Obolus matinalis* (Hall) (Pl. VIII) that a general description is unnecessary. It varies from that species in the shorter, more transverse dorsal valve, and the narrower outline of the ventral valve toward the beak.

This species occurs in great abundance in the thin-bedded limestone in the upper portion of the Cambrian section of the Teton Range, Wyoming, in association with *Billingsella coloradoensis* (Shumard) and *Lingulella (Lingulepis) acuminata meeki* (Walcott). The forms from this horizon are illustrated by Plate X, figures 5, 5a, and 5b. What appears to be the same species occurs nearly 700 feet lower in the section in a thin-bedded sandstone. Specimens from this horizon are represented by Plate X, figures 5c and 5d. The dorsal valve (5d) is broader and more transverse posteriorly than the dorsal valve from the upper horizon.

This form owes its specific name to its occurrence in the Teton Mountains of Wyoming.

FORMATION AND LOCALITY.—**Upper Cambrian:** (161) Limestone on the south side of West Gallatin (Gallatin) River, northwest of Hamilton on the north side of the Gallatin Valley; (152b)^a east side of Dry Creek, below Pass Creek, Threeforks quadrangle (U. S. Geol. Survey); and (148a) limestone of the Gallatin formation at the head of Bostwick Canyon [Iddings and Weed, 1894, areal geology sheet^b], in the Bridger Range, Livingston quadrangle (U. S. Geol. Survey); all in Gallatin County, Montana.

Middle Cambrian: (4m) Sandstones about 150 feet (45.7 m.) above the unconformable base of the Cambrian; and (4e) limestones about 950 feet (289.6 m.) above the unconformable base of the Cambrian; both in the divide at the head of Jackson Creek (locally known as Sheep Creek), a creek flowing into Jackson Lake about 0.5 mile (0.8 km.) south of its northwestern corner, Teton Mountains, Grand Teton quadrangle (U. S. Geol. Survey), Uinta County, Wyoming.

(4h) About 375 feet (114.3 m.) above the base of the Cambrian in limestone interbedded in the Flathead shales of Peale [1893, p. 21], 1 mile (1.6 km.) north of the junction of East Gallatin and West Gallatin (Gallatin) rivers, 4 miles (6.4 km.) east-northeast of Logan, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County; and (4x) limestone interbedded in the Wolsey shale [Weed, 1900, p. 285], at the base of a butte in Belt Park, about 6 miles (9.6 km.) northwest of Neihart, Little Belt Mountains quadrangle (U. S. Geol. Survey), Cascade County; both in Montana.

(3e) Thin-bedded limestones less than 400 feet (121.9 m.) above the quartzitic sandstones of the Cambrian, at Ophir, Oquirrh Range, Tooele County, Utah.

(14x) About 400 feet (122 m.) above the bottom of Tombstone Gulch in the Abrigo limestone [Ransome, 1904, p. 3], in the northwest suburb of Bisbee [Ransome, 1904, areal geology sheet], Cochise County, Arizona.

OBOLUS TETONENSIS LEDA Walcott.

Obolus tetonensis leda WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 63. (Characterized as below as a new variety.)

This is the Upper Cambrian representative of *Obolus tetonensis* Walcott of the Middle Cambrian of the Teton Mountains. Stratigraphically it occurs over 2,000 feet higher in the Cambrian

^a This species is somewhat doubtfully identified from this locality.

^b Iddings, J. P., and Weed, W. H., Livingston folio (No. 1), Geol. Atlas U. S., U. S. Geol. Survey, 1894.

section, and the localities are 400 miles apart. The variety *leda* differs from the species in having more numerous fine threadlike striæ and in having the ventral valve on the average more obtuse in old shells.

FORMATION AND LOCALITY.—Upper Cambrian: (30m) About 1,950 feet (584.4 m.) above the Middle Cambrian and 1,350 feet (411.5 m.) below the top of the Upper Cambrian in the siliceous limestones forming 1e of the Notch Peak limestone [Walcott, 1908f, p. 175], on the slopes of Notch Peak, about 5 miles (8 km.) southwest of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.

OBOLUS TETONENSIS NINUS Walcott.

Plate VIII, figures 11–o; Plate XI, figures 1, 1a–g.

Obolus tetonensis ninus WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 328. (Characterized essentially as below as a new variety.)

This variety differs from *Obolus tetonensis* Walcott and from *O. matinalis* (Hall) by the more elongate form of the dorsal valve and the more acuminate form of the ventral valve, the cardinal slopes of the latter extending much farther forward in the variety *ninus* than in the two species.

The advanced position of the visceral area in the ventral valve is shown by Plate XI, figure 1b, and in the dorsal valve by Plate XI, figure 1g. The advanced position of the latter may be compared with the visceral area of *Obolus (Schmidtia) crassus* Mickwitz.

FORMATION AND LOCALITY.—Upper Cambrian: (12m) Arbuckle limestone (in the section 7 miles (11.2 km.) north of Springer this horizon is about 30 feet (9.1 m.) above the Reagan sandstone), NE. $\frac{1}{4}$ sec. 2, T. 2 S., R. 1 E., Ardmore quadrangle (U. S. Geol. Survey), Carter County; (12k) limestones of the Reagan sandstone (in the section 7 miles (11.2 km.) north of Springer this horizon is about 225 feet (69 m.) above the porphyry contact and 55 feet (17 m.) below the Arbuckle limestone), on the west side of Honey Creek, near the southeast corner of sec. 35, T. 1 S., R. 1 E., Ardmore quadrangle (U. S. Geol. Survey), Carter County; (12n) limestones of the Reagan sandstone (15 feet above 12k in the Springer section), NW. $\frac{1}{4}$ sec. 1, T. 2 S., R. 1 E., Ardmore quadrangle (U. S. Geol. Survey), Carter County; and (12p) about 225 feet (69 m.) above the igneous rocks in the limestones of the Reagan sandstone, at the northwest extremity of the Arbuckle Mountains, about 4 miles (6.4 km.) east of Homer, Carter County; all in Oklahoma.

(9q) About 10 feet (3 m.) above the porphyry contact and 90 feet (27.4 m.) below the Arbuckle limestone, in limestones of the Reagan sandstone, in middle of W. $\frac{1}{2}$ sec. 2, T. 4 N., R. 13 W.; (9p, 9r, and 9t)^a from 45 to 170 feet (14 to 52 m.) above the porphyry contact in the limestones of the Reagan sandstone, in SE. $\frac{1}{4}$ NE. $\frac{1}{4}$ sec. 2, T. 4 N., R. 13 W.; (9s) about 85 feet (26 m.) below the Arbuckle limestone in the limestones of the Reagan sandstone, near middle of W. $\frac{1}{2}$ sec. 13, T. 4 N., R. 13 W.; and (9u) about 195 feet (59.4 m.) above the porphyry contact in the limestones of the Reagan sandstone in SE. $\frac{1}{4}$ NE. $\frac{1}{4}$ sec. 2, T. 4 N., R. 13 W.; all about 15 miles (24.2 km.) northwest of Fort Sill, Comanche County, Oklahoma.

(68) Interbedded sandstone and limestone, Packsaddle Mountain, Llano County, Texas.

(54w) Limestone of the St. Charles formation [Walcott, 1908a, p. 6], about 250 feet (76 m.) above the Middle Cambrian on the north side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

OBOLUS ? TORRENTIS Matthew.

Obolus torrentis MATTHEW, 1902, Trans. Roy. Soc. Canada, 2d ser., vol. 8, sec. 4, No. 3, p. 94, Pl. I, fig. 1. (Mentioned as a new species.)

Obolus torrentis MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, p. 76, Pl. VIII, fig. 1. (Described and discussed as a new species. Fig. 1 is copied from fig. 1 of the preceding reference.)

The type material representing this form is too imperfect for specific determination. A crushed and distorted dorsal valve, and the interior of a crushed ventral valve that suggests *Lingulella triparilis* (Matthew) (Pl. XLV) are all Doctor Matthew sent me. The difference in stratigraphic horizon between the shales containing *O. ? torrentis* and the shales bearing *Lingulella triparilis* is not great, and but for the presence of an interbedded mass of "felsites" they would probably have been considered as belonging to one formation.

The specific name is derived from its occurrence near the great falls (torrent) in Dugald Brook.

FORMATION AND LOCALITY.—Middle Cambrian: (13k)^b Shales of Matthew's [1903, p. 15] Coldbrook, above the great falls in Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia.

^a 9r is the type locality.

^b The specimens to which Locality 13k was assigned were collected one year later than those described by Doctor Matthew [1902, p. 94] but from the same locality.

OBOLUS TRIANGULARIS Mickwitz.

Obolus triangularis MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 145-147, Pl. II, figs. 7-9. (Described and discussed in German as a new species; see below for translation of diagnosis.)

Obolus triangularis inornatus MICKWITZ, 1896, idem, pp. 148-149, Pl. II, figs. 10-12. (Described and discussed in German as a new variety.)

Obolus triangularis MICKWITZ, MOBERG and SEGERBERG, 1906, Medd. från Lunds Geol. Fältklubb, Ser. B, No. 2 (Aftryck ur K. Fysiografiska Sällskapets Handl., N. F., Bd. 17), p. 65. (New locality mentioned in Swedish.)

Obolus triangularis MICKWITZ, WESTERGÅRD, 1909, Medd. från Lunds Geol. Fältklubb, Ser. B, No. 4 (Aftryck ur K. Fysiografiska Sällskapets Handl., N. F., Bd. 20), p. 56. (Locality mentioned in Swedish.)

The original description by Mickwitz follows:

Shells moderately large, slightly grooved, thin, brittle; outline of shell subtriangular, posterior border of shells rectilinear, not winged; surface slightly shiny, concentric striæ in fine ribs, which converge to the border of the shell, either diverging or confluent, running somewhat irregularly, separated by deep, rounded grooves; radial striæ dwindling, indefinite. Area large, splanchnocœlic part broad, peduncular groove wide, parallel bordered, opening toward the inside of the shell. Central groove of the large shell heart-shaped to subpentagonal, slightly swelled. Median septum and lateral septa perceptibly developed. Sinus of small shell reaching nearly to the area, corneous processes ridge-shaped. Combined central places for the attachment of muscles of the large shells are not prolonged into grooves posteriorly.

Mickwitz states that the shells of this species are very thin and brittle and that in the enormous mass of loose *Obolus* conglomerate that he examined at Joa not one thick-shelled specimen was found. The shell also occurs alone at Reval under the *Obolus* conglomerate, and they are so delicate that they can not be taken from the matrix, although it is a very loose, fine-grained sandstone. The thick shells of the *Obolus* conglomerate have a more confused ornamentation and a somewhat wider form. The concentric ribs of the typical form have the best development near the center of the shell, where they run together and are dotted in places with indistinct knots formed by the intersection of the irregularly developed radial striæ with the concentric striæ. He calls attention to the broad pedicle groove of the ventral valve, which is of the same type as that of *O. panderi* Mickwitz, and describes in detail the interior markings of the valves.

The variety *inornatus* does not appear to me to be sufficiently distinct to be entered as a variety.

FORMATION AND LOCALITY.—Upper Cambrian: (395g) *Obolus conglomerate* at Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; (395i) *Obolus conglomerate* at Ilgast; and (336i) sandstone below the *Obolus conglomerate* proper, at Reval; all [Mickwitz, 1896, p. 147] in the Government of Esthonia, Russia.

(9d) *Obolus* sandstone at Jaggowal, about 20 miles (32 km.) east-southeast of Reval, Government of Esthonia, Russia.

(310n) *Obolus* sandstone? [Moberg and Segerberg, 1906, p. 65], in Dalarna, Province of Kopparberg, Sweden.

OBOLUS VOLBORTHI Mickwitz.

Obolus volborthi MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 155-157, Pl. II, figs. 16-17. (Described and discussed in German as a new species.)

This species is separated from *O. eichwaldi* Mickwitz on the difference in the character of the surface. Of this species only three fragments have been found. According to Mickwitz, it is distinguished from *O. eichwaldi* by its oval outline and pronounced inclination of the beak. He gives a detailed description and comparison, to which the student is referred.

The specific name was given in honor of Dr. A. von Volborth.

FORMATION AND LOCALITY.—Upper Cambrian: (395 [Mickwitz, 1896, p. 157]) *Obolus* sandstone at Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval, Government of Esthonia, Russia.

OBOLUS WILLISI (Walcott).

Plate XXIII, figures 1, 1a-j.

Obolus (Lingulella) willisi WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, pp. 418-419. (Described and discussed as below as a new species.)

General form broadly ovate, with the ventral valve obtusely acuminate and the dorsal valve almost transversely ovate, the posterior margin being very broadly obtuse; convexity moderate in the specimens preserved in the calcareous sandstone. Surface of shell marked by concentric lines and striæ of growth, with very fine irregular striæ between them; a few specimens show very narrow, slightly irregular, interrupted, radiating ridges or undulations (Pl. XXIII, fig. 1j); inner surface of the shell more or less strongly pitted or punctate. This character varies greatly in casts from the same layer of shale, as may be seen by comparing Plate XXIII, figure 1b, where it is extreme, with Plate XXIII, figures 1a, 1e, and 1h. The shell, as preserved in the argillaceous shale, is relatively thin.

The largest ventral valve, which is shortened slightly by distortion, has a length of 10 mm.; width, 8.5 mm. A well-preserved dorsal valve 8.5 mm. in length has the same width, while another associated dorsal valve 6.5 mm. in length has a width of 7 mm.

As shown in the casts, the area of the ventral valve is rather long and is divided midway by a strong cast of the pedicle furrow, and again midway between the pedicle furrow and the lateral margins by a well-defined flexure line; fine striæ of growth cross the area parallel with its base. The area of the dorsal valve is relatively short and extends far out onto the cardinal slopes; it is marked by clearly defined but not strong flexure lines. Casts of the interior of the ventral valve show traces of the visceral cavity (v) and the main vascular sinuses (vs). In the dorsal valve a narrow median septum is all that is shown, with the exception of faint indications of the central and anterior lateral scars (h and j) (Pl. XXIII, fig. 1g) and what appears to be the transmedian (i) (Pl. XXIII, fig. 1e).

Observations.—This species was at first compared with *Obolus lamborni* (Meek) (Pl. XXII). Like that, it has a strongly pitted or punctate inner surface, and the ventral valve has the same general outline. The dorsal valve, however, is much more transverse and obtuse, and the central muscle scars in the dorsal valve appear to be somewhat differently located.

This species has considerable vertical range; some of the specimens associated with the Middle Cambrian fauna in the Conasauga shale are very much like *O. lamborni* from the Rogersville shale of Tennessee.

I take pleasure in naming the species in honor of Mr. Bailey Willis, who for a considerable time had charge of the work in the region where these specimens were collected by Dr. Cooper Curtice.

FORMATION AND LOCALITY.—**Upper Cambrian:** (93) Shales and limestones at the base of the Knox dolomite, near Jordan's, just below the ford on Cowan Creek; (93n) shales in the southern part of Jordan's farm, near Jordan's crossroads; and (93x) shales on the Clarke farm, near the ford across Cowan Creek, about 2 miles (3.2 km.) north of Jordan's crossroads; all about 8 miles (12.8 km.) southeast of Center, Cherokee County, Alabama.

(96b) Shales in a railroad cut on the Southern Railway, near Cave Spring, 10 miles (16.1 km.) southwest of Rome, Floyd County, Georgia.

(122) Shale southwest of Town Knobs, 1 mile (1.6 km.) northwest of Rogersville, Hawkins County, Tennessee.

Middle Cambrian: (146) Conasauga shale on the Jacksonville road, 8 miles (12.8 km.) east of Center; (91) Conasauga shale at Cedar Bluff; (94) shales 0.25 mile (0.4 km.) beyond Steel Ford, Cowan Creek, about 8 miles (12.8 km.) southeast of Center; and (94a) Conasauga shale, in Coosa Valley, east of Center; all in Cherokee County, Alabama.

(140a) Shales 200 yards (182.9 m.) east of Thomas Mills, 5 miles (8 km.) north of Cave Spring [Hayes, 1902, historical geology sheet], Floyd County, Georgia.

(101b) Rogersville shale, just east of the schoolhouse, 3.5 miles (5.6 km.) southwest of Rogersville, on the road to Melinda Ferry [Keith, 1896a, areal geology sheet], Hawkins County; (107a and 107b) shales and sandstone of the Rome formation in railroad cut in Bull Run, northwest of Copper Ridge [Keith, 1896b, areal geology sheet], 11 miles (17.6 km.) northwest of Knoxville, Knox County; (14a) sandstone of the Rome formation along First Creek Gap, 4 miles (6.4 km.) north-northeast of Knoxville [Keith, 1905, areal geology sheet], Knox County; (106a) reddish-brown shales in middle of valley east of Shooks Ridge, in Bays Mountains, 10 miles (16.1 km.) southeast of Knoxville, Knox County; (374e) shales collected near the State line, 2.25 miles (3.6 km.) north of Peltier, Estillville quadrangle (U. S. Geol. Survey), Sullivan County; and (121) Rogersville shale, road just east of Harlan Knob, 4 miles (6.4 km.) northeast of Rogersville [Keith, 1905, areal geology sheet], Hawkins County; all in Tennessee.

OBOLUS WORTHENI Walcott.

Text figures 39A-D; Plate IX, figure 5e.

Obolus wortheni WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 63-64, Pl. VII, fig. 17. (Described and discussed as below as a new species. Fig. 17, the type specimen, is copied in this monograph, Pl. IX, fig. 5e.)

General form subcircular, with the ventral valve very obtusely acuminate and the dorsal valve slightly transverse; both valves slightly convex. Ventral valve with the beak at the posterior margin, which rises slightly from the general plane of the margin of the valve; the minute beak of the dorsal valve is at the posterior margin.

Surface marked by sharp, fine, concentric striæ and fine imbricating lines of growth; on some shells low, irregular, more or less obscure and interrupted radiating ridges occur. Shell of medium thickness and built up of several layers or lamellæ. The average diameter of the valves is 3 mm.

The interior of the ventral valve shows a short flat area divided midway by a narrow pedicle furrow; the visceral area, which is about one-third the length of the valve, is shown only in outline; the main vascular sinuses are strong and situated about midway between the median line and the lateral margins of the valve; the surface outside the visceral area in both valves is marked by fine concentric furrows and large scattered punctæ, much like those of *Obolus (Westonia) escasoni* (Matthew) (Pl. XLIX, figs. 1a and 1aa). The interior of the dorsal valve has a short area with a broad pedicle groove; strong curved main vascular sinuses extend from beneath the area well toward the front of the valve; they are subparallel to the margin and are situated about one-third the distance from the margin to the median line of the valve; the visceral area is outlined in about one-half the length of the valve; a narrow, deep sinus extends from each side of the anterior end and then curves outward to the front margin (Pl. IX, fig. 5e).

FIGURE 39.—*Obolus wortheni* Walcott. A, Exterior of ventral valve (U. S. Nat. Mus. Cat. No. 51638b). B, Exterior of dorsal valve (U. S. Nat. Mus. Cat. No. 51638c). C, Interior of ventral valve (U. S. Nat. Mus. Cat. No. 52431). D, Interior of ventral valve (U. S. Nat. Mus. Cat. No. 51638d).

The specimens represented by figures 39A, 39B, and 39D are from Locality 54u, that represented by figure 39C is from Locality 54t, both near Malade, Idaho.

Observations.—This shell was at first thought to be the young of *Obolus tetonensis* Walcott, but with the finding of a good series it was found to have a nearly circular ventral valve instead of subacuminate as in *O. tetonensis*, and it is less convex in the same character of matrix. In form *Obolus wortheni* resembles *Obolus discoideus* (Hall and Whitfield) (Pl. XVIII, figs. 6, 6a-d), but it differs in being more circular in outline and in having a thinner shell.

The specific name was given in honor of A. H. Worthen.

FORMATION AND LOCALITY.—Upper Cambrian: (5a, 5c, 54t, and 54w) Limestone about 250 feet (76 m.) above the Middle Cambrian; (54x) limestone about 200 feet (60.4 m.) above the Middle Cambrian; and (54u) limestone about 100 feet (30.2 m.) above the Middle Cambrian; all in the St. Charles formation [Walcott, 1908a, p. 6], on the north side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

Middle Cambrian: (54v) Limestone in the lower part of the Bloomington formation [Walcott, 1908a, p. 7], about 1,600 feet (488 m.) below the Upper Cambrian, on the south side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

OBOLUS ZETUS (Walcott).

Plate XXV, figures 3, 3a-c.

Obolus (Lingulella) zetus WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 419. (Characterized and discussed as below as a new species.)

This is a small shell that has somewhat the general form of *Obolus lamborni* (Meek). It differs, however, in being more transverse across the front, in having a broad, shallow

depression in the dorsal valve, and also in being flattened across the center of the ventral valve. It occurs at a higher horizon than *Obolus* (*Westonia*) *chuarensis* (Walcott), *O.* (*W.*) *euglyphus* (Walcott), and *Lingulella lineolata* (Walcott) of the upper beds of the "Tonto" sandstone. It has more the form of the true *Obolus* than those species, but its shell is relatively thin and marked by fine radiating striae. All of its essential characters are well shown by the figures illustrating the species.

FORMATION AND LOCALITY.—Upper Cambrian: (75) Thin-bedded limestones just below the base of the Ordovician in the Tonto group, near the water's edge at the mouth of Kanab-Canyon, Grand Canyon of the Colorado, Arizona.

Middle Cambrian: (74) Sandstone about 300 feet (91.4 m.) above the base of the Tonto group, at the head of Nunkowcap Valley, Grand Canyon of the Colorado, Arizona.

(358b) Limestone on the southwest side of Escabrosa Ridge, 4.5 miles (7.2 km.) west-southwest of Bisbee, Arizona.

OBOLUS? ZOPPI Walcott.

Plate XXX, figures 16, 16a-b.

Obolella crassa BORNEMANN [not HALL], 1891, Nova Acta Acad. Cæs. Leop.-Carol. Germanicæ Naturæ Curiosorum, Bd. 56, No. 3, pp. 439-440, Pl. XIX, figs. 15-17. (Described and discussed in German; see below for translation. Figs. 16, 17a, and 17b are copied in this monograph, Pl. XXX, figs. 16a, 16, and 16b, respectively, 16b being the side view of the specimen represented by fig. 16.)

Obolus? zoppi WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, pp. 684-685. (Original description translated and species discussed as below as a new species.)

The original description by Bornemann follows:

Broadly oval or circular, with somewhat pointed vertex. Shells strongly arched, one somewhat more so than the other. They are marked with prominent concentric lines; no radial striation is noticed. Found in a red-yellow sandstone layer not far from the houses of Canal Grande on the road to Punta Pintau, Sardinia.

In view of the imperfect state of preservation, a determination can only be based on the outer form, whose habit agrees with the American species from the Cambrian limestone of Troy.

Bornemann kindly sent me two specimens of this form. They suggest *Obolella crassa* (Hall) in form and outline, but the material is too imperfect to identify the species or genus. I find in one specimen indications of the presence of a high area that rises slightly above the plane of the ventral valve. In two casts there is nothing to suggest the cast of the pedicle aperture, which is usually well preserved in casts of the ventral valve of specimens of *Obolella atlantica* Walcott. As the material is probably from the Middle-Cambrian, a provisional reference is made to *Obolus*.

FORMATION AND LOCALITY.—Middle Cambrian: (354f [Bornemann, 1891, p. 439])^a Reddish-yellow sandstone near the houses of Canal Grande on the road to Punta Pintau, island of Sardinia, Italy.

OBOLUS sp. undt. a.

Plate X, figure 4.

A small *Obolus*-like shell, which occurs in the dark argillaceous shales above the Upper Cambrian zone of eastern New York, resembles in outline *Obolus* (*Bröggeria*) *salteri* (Holl) (Pl. XIII) of England and Sweden. All the specimens are flattened in the shale. No distinctive specific characters except a series of well-defined concentric striae are shown.

FORMATION AND LOCALITY.—Ordovician: (338v) Shale 1 mile (1.6 km.) southwest of Middle Granville, Mettawee quadrangle (U. S. Geol. Survey), Washington County, New York.

OBOLUS sp. undt. b.

A small shell marked by very distinct concentric striae and very faint radiating striae occurs at the following locality. The material is too imperfect for illustration.

FORMATION AND LOCALITY.—Upper? Cambrian: (7n) Limestone at Hornet Spring in the Spring Mountain Range, on road from Indian Spring to Pahrump Valley, Lincoln County, Nevada.

^a Specimens from this locality are included in the collections of the United States National Museum.

OBOLUS sp. undt. c.

An exfoliated dorsal valve, probably belonging to the genus *Obolus*, occurs at the following locality. The specimen is too imperfect for identification.

FORMATION AND LOCALITY.—Ordovician: (214a) Limestone near the base of the Pogonip limestone in the White Pine district, White Pine County, Nevada.

OBOLUS sp. undt. d.

In the conglomerate limestone near Highgate Falls, Vermont, I collected a single specimen of the ventral valve of a species of *Obolus* not unlike the ventral valve of *Obolus mæra* (Hall and Whitfield) (Pl. X) of the Rocky Mountain region.

Its surface is marked by numerous fine radiating striæ and by distinct, concentric, lamellose lines of growth. The fossils associated with it in the same fragment of limestone indicate the Upper Cambrian horizon.

FORMATION AND LOCALITY.—Upper Cambrian: (87') Conglomeratic limestone 1 mile (1.6 km.) south-southwest of Highgate Falls, Franklin County, Vermont.

OBOLUS sp. undt. e.

Plate XV, figure 8.

Obolus sp. KAYSER, 1876, Beiträge zur Geologie und Paleontologie der argentinischen Republik, vol. 2, Paleontol. Theil, Abth. 1, pp. 9–10, Pl. I, fig. 14. (Described and discussed in German. Fig. 14 is copied in this monograph, Pl. XV, fig. 8.)

This form is illustrated by a single specimen of what appears to be the ventral valve. Kayser [1876, p. 9] states that most of the specimens are mere fragments and only the genus can be determined. He suggests that it may be *Obolella*, but from our present knowledge of that genus it is not probable. The figure recalls forms of *Obolus matinalis* (Hall) and *O. anceps* Walcott.

FORMATION AND LOCALITY.—Upper Cambrian: (389b [Kayser, 1876, p. 9]) Sandstone at Tilcuya, Province of Jujuy, Argentina, South America.

OBOLUS? sp. undt. f.

Plate XV, figure 9.

Lingulella sp. KAYSER, 1883, China, by Richthofen, vol. 4, p. 35, Pl. III, fig. 2. (Characterized and discussed in German. Fig. 2 is copied in this monograph, Pl. XV, fig. 9.)

Kayser [1883, p. 35] states that the remains of this species available for study are too imperfect to permit accurate description and comparison. The shell preserves traces of radial striation and strong concentric striæ of growth. Attention is called to the fact that it has a somewhat similar outline to *Lingulella nathorsti* Linnarsson (Pl. XXXI).

The resemblance to the *Obolus* described by Kayser [1876, p. 9] from Tilcuya, Argentina, is noticeable, and like that species it recalls *Obolus matinalis* (Pl. VIII). Comparison should also be made with *Dicellomus politus* (Hall).

FORMATION AND LOCALITY.—Upper Cambrian: (332 [Kayser, 1883, p. 35]) Limestone at Saimaki, Province of Liaotung, China.

OBOLUS sp. undt. g.

Obolus (?) sp. indet., LINNARSSON, 1876, Bihang till K. svensk. Vet.-Akad. Handl., Bd. 3, No. 12, p. 13, Pl. III, fig. 31. (Described and discussed in English. See below for copy of description.)

The original description by Linnarsson follows:

Because of its general shape, I refer to the genus *Obolus* a species of which the materials are very unsatisfactory, so that I will not create for it a specific name, though it is easily distinguished from all the primordial Brachiopoda of Sweden. The best specimen is an interior, somewhat mutilated anteriorly, and with the innermost shell layers partly exfoliated. Its width is 16 mm., the length about 14 mm. The shell is very slightly convex; its circumference resembles a sector of a circle; the front is broadly rounded; the slopes forming the beak seem to be nearly straight, and make a

somewhat obtuse angle. The surface is not well preserved in any specimen; judging, however, from some small fragments, I should think that a concentric striation is prevailing, but that there are also radiating ribs. In the inner shell layers little more than a longitudinal striation is seen; the innermost are perforated by small punctiform pits. The inner layers are polished and glossy; the outermost seems to be opaque.

FORMATION AND LOCALITY.—Middle Cambrian: (3201 [Linnarsson, 1876, p. 16]) Drift blocks supposed to have come from the *Paradoxides alandicus* zone [Linnarsson, 1876, p. 6], at Lillviken, near Oestersund, Province of Jemtland, Sweden.

BRÖGGERIA Walcott,^a subgenus of **OBOLUS**.

Obolus (*Bröggeria*) WALCOTT, 1902, Proc. U. S. Nat. Mus., vol. 25, p. 605. (Characterized as below as a new subgenus.)
Obolus (*Bröggeria*) WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 144. (Classification of genus.)

This subgenus differs from the typical forms of *Obolus* in having a very deep visceral depression in both valves and a minutely punctate interior surface. A series of shells showing the effect of compression on the appearance of the interior casts of the valves is illustrated on Plate XIII.

Type.—*Obolella salteri* Holl.

The generic name was given in honor of Dr. W. C. Brögger.

OBOLUS (BRÖGGERIA) **SALTERI** (Holl).

Obolus? *salteri* (Holl), MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, p. 19. (Discussed in German.)

Obolella (?) *salteri* Holl, MATLEY, 1902, Quart. Jour. Geol. Soc. London, vol. 58, pt. 1, pp. 139-140, figs. 3-6, p. 138. (Described and discussed.)

Obolus (*Bröggeria*) *salteri* (Holl), WALCOTT, 1902, Proc. U. S. Nat. Mus., vol. 25, pp. 605-606. (Original description, Holl, 1865, p. 102, copied as below, and species discussed essentially as below.)

Obolus (*Bröggeria*) *salteri* (Holl), MÖBERG and SEGERBERG, 1906, Medd. från Lunds Geol. Fältklubb, Ser. B, No. 2 (Aftryck ur K. Fysiografiska Sällskapets Handl., N. F., Bd. 17), p. 64, Pl. I, figs. 27-30. (Described and discussed in Swedish.)

Obolus (*Bröggeria*) *salteri* var.? WESTERGÅRD, 1909, Medd. från Lunds Geol. Fältklubb, Ser. B., No. 4 (Aftryck ur K. Fysiografiska Sällskapets Handl., N. F., Bd. 20), p. 56, Pl. II, figs. 17-19. (Discussed in Swedish. Figs. 17 and 18 are copied from Moberg and Segerberg, 1906, Pl. I, figs. 28 and 27, respectively.)

The original description by Holl follows:

Compressed, subtriangular to nearly round, rather broader than long; shell thin; surface grooved concentrically by a few inequidistant, strongly marked lines of growth and by numerous finer lines which are distinct only on the sides of the shell. Length usually about one-third inch, width slightly more.

Position.—In the Black Shales.

Brögger [1882, Pl. X, figs. 10, 11, and 13] identified this species from both the *Ceratopyge* slate and the *Ceratopyge* limestone of Sweden. The specimen from the limestone is very beautifully preserved and appears to be the dorsal valve of this species.

^a The synonymy for this subgenus does not give a complete record of the various genera under which the species now included in *Bröggeria* were formerly placed; it gives only those references in which the genus is discussed or described. To complete the record the following mere generic references are listed:

Obolella Holl [1865, p. 102].

Obolella Davidson [1866, p. 61; 1868, p. 163].

Obolus? Dall [1870, p. 163].

Obolella Phillips [1871, p. 68].

Obolus Brögger [1882, p. 44].

Obolus? Mickwitz [1896, p. 19].

Obolella? Matley [1902, p. 139].

Obolus (*Bröggeria*) Moberg and Segerberg [1906, p. 64].

I find in the limestone from Slemmestad a broad form of the ventral valve that closely resembles in outline and surface the shell illustrated by Brögger as "*Lingula* sp." [Brögger, 1882, Pl. X, fig. 9], and I think that the specimen represented by figure 12 of the same reference ("*Lingula* sp.") may also belong to this species.

Through the courtesy of Doctor Brögger, I studied the material representing this species collected in Norway, including the fine interior of the dorsal valve illustrated on Plate XIII, figure 1m, of this monograph.

In a collection kindly sent me by Dr. G. Lindström I find two ventral valves (Pl. XV, figs. 4a and 4b) from the black shale of Skåne, but it is in the collection made by Mr. Schmalensee that specimens occur showing the casts of the interior of the dorsal valve. These have the imprint of the central visceral area, the large vascular sinuses, and the area (Pl. XV, fig. 4c). A cast (Pl. XIII, fig. 1b) of an uncompressed shell proves that the visceral area was short and relatively small. Comparing the latter figure with Plate XIII, figure 1m, I am led to conclude that the latter is a partly exfoliated specimen preserving the vascular markings on the thin inner layers of the shell.

In Cape Breton this species occurs abundantly in association with *Lingulella concinna* Matthew and *Acrotreta bisecta* Matthew. The shells are all compressed in the shale, but a direct comparison of the interiors of the valves of specimens from Cape Breton and the *Ceratopyge* shales of Sweden shows the two to be identical in all characters except the length of the area and pedicle groove. The Cape Breton shells have a longer area, but whether or not this is due to the conditions of preservation I am unable to decide, as the material from Sweden is very imperfect about the area. On one of the Cape Breton shells the fine punctæ of the interior surface are clearly shown.

The specific name was given in honor of Mr. J. W. Salter.

FORMATION AND LOCALITY.—Passage beds between the Upper Cambrian and the Ordovician: (8x) *Ceratopyge* limestone at Slemmestad, about 3 miles (4.8 km.) southwest of Christiania; (323i [Brögger, 1882, description of Pl. X]) *Phyllograptus* slate at Krekling, in Sandsvår; (323e [Christiania Univ. Min. Inst.]) *Ceratopyge* limestone (Étage 3a γ of Brögger) at Engervik, in the Christiania region; (323f [Brögger, 1882, pp. 16–17]) lower part of the *Ceratopyge* limestone at Vestfossen, 10 miles (16.1 km.) west-southwest of Christiania; and (323h [Brögger, 1882, p. 17]) blue *Ceratopyge* limestone (a higher horizon than 323f) at Vestfossen, 10 miles (16.1 km.) west-southwest of Christiania; all in Norway.

(309 [Moberg and Segerberg, 1906, description of Pl. I]) *Ceratopyge* limestone (zone 4 of Moberg and Segerberg) at Fogelsång, 5 miles (8 km.) east of Lund; and (323j [Brögger, 1882, p. 44]) *Ceratopyge* limestone at Tosterup; both in the Province of Malmöhus, Sweden.

Upper Cambrian: (304e [Davidson, 1866, p. 62]) *Upper part of the black "White Leaved Oak" shales at Coal Hill, east end of the Malvern Hills*; and (304a [Groom, 1902, p. 110]) "*Bronsil*" shales in the Malvern Hills; both between Herefordshire and Worcestershire, England.

(3a) Shale in Barachois Glen, 4 miles (6.4 km.) south of Little Bras d'Or Lake; (10c) shale on west side of Barachois River; (10d) shales on west side of Barachois River, 0.125 mile (0.2 km.) north of Boisdale road, opposite McMullin's place; (10m) shales 2 miles (3.2 km.) south of the Boisdale road from Upper Leitches Creek, toward the head of Barachois River; (10e, 10f, and 10g) shales on the east branch of Barachois River, 0.5 mile (0.8 km.) north of the crossroad from Boisdale to Upper Leitches Creek; (10i) shale in high bank on west side of Barachois River, just north of the Boisdale road; (10l) shale on east bank of Barachois River, 6 miles (9.6 km.) from Little Bras d'Or Lake; (3h) shale and shaly limestone on McNeil Brook, 1.5 miles (2.4 km.) east of Marion Bridge; (10n) shale in ravine on east side of Barachois Glen, 3 miles (4.8 km.) from Barachois; (13h) shale on east bank of Barachois River, 1.5 miles (2.4 km.) north of Boisdale; and (10r) arenaceous shales of Division C3a? of Matthew at McAdam Shore, East Bay, east of Bras d'Or Lake; all in eastern Cape Breton, Nova Scotia.

(323w) Black argillaceous shale of Étage 3a β at Christiania, Norway.

(309i) Limestone band in *Ceratopyge* slate at Borgholm; (309j) shale at Alunbruk (alum works); (310d) *Ceratopyge* slate at Borgholm; and (321x) *Dictyograptus* slate at Alunbruk (alum works); all on Oeland Island, Sweden.

(390g [Moberg and Segerberg, 1906, p. 64])^a Limestone in the *Dictyograptus* slate at Sandby, 6 miles (9.6 km.) east-northeast of Lund; (309h) limestones of the *Dictyograptus flabelliformis* zone at Fogelsång, 5 miles (8 km.) east of Lund; (323k [Brögger, 1882, p. 44]) *Ceratopyge* slate at Tosterup; and (309i) limestones at Sandby, 6 miles (9.6 km.) east-northeast of Lund; all in the Province of Malmöhus, Sweden.

Upper? Cambrian: (3091) Shale collected somewhere in Sweden, exact locality unknown; and (310h) shale collected somewhere (probably Fogelsång) in the old province of Skåne, now the Provinces of Malmöhus and Christianstad; both in Sweden.

^a Specimens from this locality are included in the collections of the United States National Museum.

PALÆOBOLUS Matthew,^a subgenus of OBOLUS.[*palæobolus*, ancient; and *Obolus*.]

- Palæobolus* MATTHEW, 1899, Bull. Nat. Hist. Soc. New Brunswick, vol. 4, pt. 3, No. 18, pp. 201-202. (Described and discussed as a new subgenus, likely of *Obolus*, though that does not appear in the text.)
- Palæobolus* MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, pp. 140-141. (Copies the first paragraph of the preceding reference and mentions the form as a subgenus. On subsequent pages (144 and 146) the name occurs as *Obolus (Palæobolus)*.)
- Obolus (Palæobolus)* (MATTHEW), WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 144. (Classification of subgenus.)

Characterized by an approximation of the main vascular canals and surface markings. The surface is of the same type as that of *Obolus (Acritis) antiquissimus* (Eichwald) (Pl. XIII), but the position of the visceral cavity and vascular canals differs materially in the two forms.

Type.—*Palæobolus bretonensis* Matthew.

OBOLUS (PALÆOBOLUS) BRETONENSIS (Matthew).

Plate XXXII, figures 5, 5a-g.

- Palæobolus bretonensis* MATTHEW, 1899, Bull. Nat. Hist. Soc. New Brunswick, vol. 4, pt. 3, No. 18, p. 202, Pl. II, figs. 2a-i. (Described and discussed. The first reference, though it is not described as a new species.)
- Obolus bretonensis* MATTHEW, 1902, Trans. Roy. Soc. Canada, 2d ser., vol. 8, sec. 4, No. 3, p. 95, Pl. I, figs. 5a-e. (Characterized. Figs. 5a-e are copied from Matthew, 1899, Pl. II, figs. 2a-e.)
- Palæobolus bretonensis* MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, pp. 141-143, Pl. IX, figs. 2a-h. (Original description, Matthew, 1899, p. 202, copied and species redescribed and discussed. The species is mentioned on p. 143 as *Obolus bretonensis*. Figs. 2a-h of this reference are copied from Matthew, 1899, Pl. II, figs. 2a-e, 2i, 2g, and 2h. Some of the specimens used by Matthew in preparing his illustrations are copied in Pl. XXXII of this monograph. Close identification is impossible, but figs. 5, 5b, 5c, and 5e of Pl. XXXII may represent the specimens used by Matthew for figs. 2b, 2d, 2a, and 2e, respectively, of Pl. IX of his paper.)

General form rounded ovate, with the ventral valve subacuminate and the dorsal valve sometimes transversely ovate, the cardinal slope meeting at the beak to form a very broad angle. Valves moderately convex in all specimens examined. Surface of shell marked by strong, sharp, elevated, concentric ridges that merge into each other more or less toward the posterolateral edges of the shell, where they terminate on the margin (Pl. XXXII, fig. 5c); the space between the ridges slopes rapidly down into the rounded hollow and more gently up the anterior slope, which gives the effect of a subimbricated surface to the shell; fine radiating striae mark the space between the ridges, and some of the better-preserved ridges are marked by faint depressed striae; the irregularity of the ridges is most marked where they inosculate, especially toward the sides; the inner layers of the shell are marked by concentric lines of growth and fine radiating striae, and the inner surface by both sets of striae and numerous strong pits scattered over the surface and gathered like beads on the concentric growth lines. The shell is formed of the usual thin outer layer and numerous inner layers or lamellæ, but it is usually compressed in the shaly, impure sandstone so as to destroy the details of its lamellated character. The size and relative proportion of the valves are shown by the illustrations.

Casts of the interior of the ventral valve show a well-defined area that extends well out on the cardinal slopes; it is divided midway by a strong pedicle groove and again by a clear but not prominent flexure line; it is also marked by rather strong growth lines parallel to its base. Casts of the area of the dorsal valve show a rather strong area marked by lines of growth. The casts of the interior of the valves show (a) a trace of the visceral area of the ventral valve, (b) the position of the posterior of the main vascular sinuses in the ventral valve, and (c) a sharp median ridge and the bifurcation of the scars left by the vessels in front of the anterior lateral muscle scars in the dorsal valve anterior to the parietal line. The only traces of the muscle scars are in the dorsal valve, where the centrals and small anterior laterals are faintly shown

^a The synonymy for this subgenus includes only those references in which the subgenus is discussed or described. To complete the record the following mere references are listed:

Obolus Matthew [1902c, pp. 94 and 95].

Obolus (Palæobolus) Matthew [1903, pp. 144 and 146].

in an elongated shell (Pl. XXXII, fig. 5e). The approximation in position of the main vascular trunks is an unusual feature but one that, owing to the state of preservation of the material, is not altogether satisfactorily determined.

Observation.—This is a most interesting species and it is to be regretted that better material has not been found to illustrate the interior of the valves. The outer surface at once suggests comparison with *Obolus (Acritis) antiquissimus* (Eichwald) (Pl. XIII), but that species has a strong convex form and a short visceral cavity that is peculiar to it and that caused Mickwitz [1896, p. 205] to retain *Acritis* as a subgenus. The size and position of the visceral cavity is normal for the genus. Matthew [1899, Pl. II, fig. 2e] gives a diagrammatic figure of the dorsal valve in which he places large muscle scars far forward into the valve. A careful study of his specimen shows that the vascular canal in front of the anterior lateral scars bifurcates about the center of the shell. Another specimen laterally compressed (Pl. XXXII, fig. 5e) shows the central muscle scars in about the center of the shell despite the distortion of the shell. The positions given them by Matthew [1899, Pl. II] in the broad form of the shell appear to have been decided by their position in the compressed elongated shell; the same is also true of the strong median ridge in his figure 2e.

Matthew [1899, p. 201] proposes the subgenus *Palæobolus* for this species on account of the "close approximation of the vascular trunks" on the ventral valve. This character is shown in shells elongated and compressed laterally, but even by making allowance for compression they are closer than in other forms of the genus.

The specific name is derived from Cape Breton.

FORMATION AND LOCALITY.—**Middle Cambrian:** (13d') Sandstones opposite the third waterfall in Dugald Brook, between divisions E2a and E2b; (10p) sandstones just below the waterfall in Division E2b; (131' and 344i [Matthew, 1903, p. 143]) sandy shales of Division E3a; and (13n'' and 344b [Matthew, 1903, p. 142])^a *Sandy shales of Division E3d*; all in Matthew's [1903, p. 21] Etcheminian, on Dugald Brook, Indian River, Cape Breton, Nova Scotia.

(344c [Matthew, 1903, p. 142]) Sandy shales of Division E3d of Matthew's Etcheminian, on Gregwa Brook, Indian River valley; (10p') sandstone on the small brook on the hill between the bridge over Indian River and McPhees Brook; and (10r) arenaceous shales of Division C3a? of Matthew at McAdam Shore, East Bay, east of Bras d'Or Lake; all in eastern Cape Breton, Nova Scotia.

OBOLUS (PALÆOBOLUS) BRETONENSIS LENS (Matthew).

Obolus lens-primus MATTHEW, 1902, Trans. Roy. Soc. Canada for 1902, 2d ser., vol. 8, sec. 4, No. 3, pp. 94-95. (Characterized. This is the first reference to this variety.)

Obolus lens MATTHEW, 1902, idem, p. 95, Pl. I, figs. 6a-f. (Characterized.)

Obolus (Palæobolus) lens MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, pp. 144-146, Pl. X, figs. 1a-f. (Described and discussed. Figs. 1a-f are copied from figs. 6a-f, respectively, of the preceding reference.)

Obolus (Palæobolus) lens longus MATTHEW, 1903, idem, pp. 146-147, Pl. VII, figs. 4a-b. (Described and discussed as a new variety.)

Matthew [1902b, p. 95] gives a specific value to the difference in the number and closeness of the concentric striæ on the surface of the shell, but from a study of the types of *Obolus (Palæobolus) bretonensis* and material representing the surface of *O. (P.) lens* I do not think *lens* is more than a variety of *bretonensis*. The variety *longus* is based on specimens that have been compressed laterally to such an extent as to lose their original outline. With the types before me I do not feel justified in assigning them as a variety distinct from the variety *lens* with which they are associated. *O. (P.) bretonensis* occurs in beds between layers containing the variety *lens*.

Loper collected a number of specimens of a shell that may be referred to the variety *lens* in Matthew's assise 2c, in which the concentric striæ or ridges are very fine on the umbo, gradually becoming coarser toward the front, where they are of the size of the average in the typical forms of *O. (P.) bretonensis*. These shells also vary in outline so as to include the variety *longus*. In a layer just below that containing these shells he found a single shell with concentric ridges stronger and coarser than the average of *O. (P.) bretonensis*.

^a 344b is the type locality.

Matthew [1892, p. 94] uses the name *Obolus lens-primus* for a small shell of this species which was found in a lower layer of rock. The form is not illustrated or described in his larger work [Matthew, 1903], and I could not discover from the specimen that it was anything more than a young shell of the variety *lens*.

FORMATION AND LOCALITY.—Middle Cambrian: (13e) Sandstones of Division E2c; (131 and 344i [Matthew, 1903, p. 80]) sandy shales of Division E3a; (344 [Matthew, 1903, p. 144]) sandy shales of Division E3b; and (13n)^a sandstones of Division E3e: all in Matthew's [1903, p. 21] Etcheminiau, on Dugald Brook, Indian River, eastern Cape Breton, Nova Scotia.

(13m) Sandstones of Division E3f of Matthew's [1903, p. 76] Etcheminian, on Gillis Brook, Indian River, eastern Cape Breton, Nova Scotia.

FORDINIA Walcott, subgenus of **OBOLUS**.

Elkania Ford, WALCOTT (in part), 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 321-323. (Described and discussed; see under *Elkania*, p. 561, for copy. The text includes reference to species now placed under both *Elkania* and *Obolus* (*Fordinia*).)

Obolus (*Fordinia*) WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 64-65. (Characterized and discussed as below as a new subgenus.)

Obolus (*Fordinia*) WALCOTT, 1908, idem, No. 4, Pl. XI, and pp. 142 and 144. (Classification of subgenus.)

This subgenus of *Obolus* is proposed for species having a *Lingulella*-like outline and form with the development of a tendency to form a platform or thickening in the valves in connection with the attachment of the muscles in the ventral valve and a thickening in the posterior portion of the dorsal valve back of the central muscle scars. The type of the subgenus, *O. (F.) perfectus* Walcott (Pl. LXIII, figs. 10, 10a-d), has these characters well developed. The second species, *O. (F.) bellulus* (Walcott) (Pl. LI, figs. 3, 3a-f), has the cardinal area of the ventral valve more united with the visceral area than it is in *O. (F.) perfectus*, and the raised area in the dorsal valve is much smaller. In *O. (F.) gilberti* Walcott the thickened areas are much smaller than in the other two species. These three species represent a form intermediate between *Obolus* (Pls. VII and VIII) and *Elkania* (Pl. LI).

Type.—*Obolus* (*Fordinia*) *perfectus* Walcott.

The subgeneric name was given in honor of Mr. S. W. Ford.

OBOLUS (**FORDINIA**) **BELLULUS** (Walcott).

Plate LI, figures 3, 3a-f.

Elkania bellula WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 323. (Described and discussed as below as a new species.)

General form elongate oval, biconvex; beaks marginal. Surface marked by fine concentric striæ of growth that occasionally form varicæ and small ridges near the umbo; the inner layers or lamellæ have radiating striæ in addition to concentric striæ.

The shell is relatively thin and small. It rarely exceeds 2.5 mm. in length and a little less in width; the dorsal valve is somewhat shorter than the ventral.

Ventral valve subacuminate, moderately convex; the interior shows a reversed cardinal area attached to the bottom of the valve and below the plane of the margins of the valve; the pedicle groove is strong; the line of demarcation between the cardinal area and the bottom of the valve is indefinite, as the margin of the area and the body of the shell have been merged into each other; the transmedian and anterolateral muscle scars are outside the main vascular sinuses and near the margin of the valve; the central scars and middle and outside lateral scars are supposed to have been attached within the area (x) (Pl. LI, figs. 3a, 3b), as in *Obolus*; the area is largely on the front slope of the thickening of the umbonal portion of the valve.

The dorsal valve has a short reversed area, as shown in Plate LI, figure 3e; the anterolateral muscle scars were probably well advanced toward the front, judging from traces of the length of the visceral cavity.

^a 13n' is the type locality, though the specimens in the United States National Museum to which that number is assigned were collected somewhat later than Doctor Matthew's.

The vascular markings include the main vascular sinuses in the ventral valve and traces of the visceral area in the dorsal valve.

This pretty little shell is much like a small species of *Obolus* in its exterior appearance; the interior connects it with *Obolus (Fordinia) perfectus* Walcott and *O. (F.) gilberti* Walcott. I know of no species closely related to it.

FORMATION AND LOCALITY.—Upper Cambrian: (7x and 7y)^a Limestone of the Emigrant formation [Turner, 1902, p. 265], about 2.5 miles (4 km.) southeast of Emigrant Pass; and (7z) limestone of the Emigrant formation [Turner, 1902, p. 265], about 3 miles (4.8 km.) southeast of Emigrant Pass; both in the Silver Peak quadrangle (U. S. Geol. Survey), Esmeralda County, Nevada.

Specimens that are somewhat doubtfully referred to *Obolus (Fordinia) bellulus* occur at the following locality:

(54f) 150 feet (45.7 m.) above the Middle Cambrian and 1,075 feet (327.7 m.) below the top of the Upper Cambrian in the light-gray sandstone forming No. 4 of the St. Charles formation [Walcott, 1908f, p. 193], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

OBOLUS (FORDINIA) GILBERTI Walcott.

Plate LI, figures 5, 5a-d.

Obolus (Fordinia) gilberti WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 65, Pl. VII, figs. 15 and 15a. (Discussed as below as a new species. Figs. 15 and 15a are copied in this monograph, Pl. LI, figs. 5 and 5b, respectively.)

This shell was first thought to belong with *Dicellomus politus* (Hall). It differs from that species in the character of the interior of the dorsal valve and in the narrowing of the umbo as it merges into the apex. The nearest related species is *Obolus (Fordinia) bellulus* (Walcott). It differs from the latter in being more convex and in the narrowing of the umbo toward the apex.

The average size of the ventral valve is from 4 mm. to 5 mm. in length by 3 mm. to 4 mm. in width. The dorsal valve is a little shorter than the ventral.

The generic reference is based on the interior of the dorsal valve, which is similar to that of *O. (F.) bellulus* (Walcott). Associated with this species are specimens so distinct that they are doubtfully referred to the same species.

The specific name is given in honor of Mr. G. K. Gilbert, geologist, of the United States Geological Survey.

FORMATION AND LOCALITY.—Middle Cambrian: (11n) About 3,000 feet (914.4 m.) above the Lower Cambrian and 1,400 feet (426.7 m.) below the Upper Cambrian, in the upper part of the limestone forming 1a of the Marjum limestone [Walcott, 1908f, p. 179], in the long cliff 2 miles (3.2 km.) southeast of Marjum Pass [Walcott, 1908f, Pls. XIII and XV], House Range, Millard County, Utah.

OBOLUS (FORDINIA) PERFECTUS Walcott.

Plate LXIII, figures 10, 10a-d.

Obolus (Fordinia) perfectus WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 65-66, Pl. VII, fig. 16. (Described and discussed as below as a new species. Fig. 16 is copied in this monograph, Pl. LXIII, fig. 10a.)

General form elongate oval, biconvex; beaks marginal. Surface marked by concentric lines and striæ of growth that gather irregularly in small ridges on the anterior two-thirds of adult shells; very fine, obscure, radiating lines are preserved on some specimens of the outer surface. A shallow, narrow, median sinus occurs on each valve, on which the striæ arch slightly backward. Substance of shell apparently calcareoconeous. The shell is strong and built up of numerous layers or lamellæ that, except toward the beaks, are oblique to the outer layer.

Ventral valve broad ovate, with a rather blunt subacuminate beak; very young shells are broad oval in outline. Area short, and on the plane of the edges of the valve; it is divided midway by a narrow pedicle furrow that interrupts the transverse striæ of growth.

Dorsal valve a little shorter and more rounded at the beak; area short and marked by transverse striæ of growth. Both valves moderately convex.

^a7x is the type locality.

The interior of the ventral valve shows what appears to be a short continuation of the cardinal area forward into the valve before the slope into the visceral cavity; it is as though an area with lines of growth were added to the internal area of the ventral valve of *Elkania desiderata* (Billings) (Pl. LI, fig. 1). The front margin of the area merges in *O. (F.) perfectus* into the thicker shell back of the visceral cavity, much as in *O. (F.) bellulus* (Walcott). The pedicle furrow extends forward from the posterior margin across the true area and its anterior extension to the visceral cavity. The visceral area is bordered by two ridges that diverge from the sides of the pedicle furrow and extend forward about one-third the length of the valve; these ridges widen toward the front, and where they terminate there appear to be two or three minute muscle scars corresponding to the outside and middle laterals and central scars of *Obolus*; outside of the ridge there is a furrow that was probably occupied by the main vascular canal, and beyond, two narrow, elongate spaces in which the transmedian and anterior lateral muscle scars appear to be situated; all the furrows head back against the thickened shell in front of the cardinal area; the surface of the interior of the valve is marked by concentric lines and very fine radiating striae.

The dorsal valve (Pl. XLIII, fig. 10) has a short strong median ridge in front of the cardinal area, and well toward the center of the valve a narrow sharp median ridge; on each side of the latter where it begins posteriorly a small oval muscle scar (central h) occurs, and at its anterior end two elongate oval scars (anterior laterals j) that are larger than the centrals; on the thickened posterolateral portions of the valve, two small muscle scars (transmedian and outside and middle laterals, l and k) occur close to the outer margin. The surface of the visceral cavity is smooth, but in front of it the minute irregular vascular markings are very ornate; a few radiating striae also occur.

The two interiors described are unusually distinct; usually the various parts and scars are more or less obscure.

This species approaches *O. (Fordinia) gilberti* Walcott more nearly than any other species of the genus. It differs in the presence of the sinus in both valves; in being less convex; in its less pointed beak; and in its strongly marked interior. It occurs over 1,000 feet higher up in the section of the Middle Cambrian limestones than *O. (F.) gilberti*. The interior of its ventral valve is somewhat like that of *O. (F.) bellulus* (Walcott) (Pl. LI, fig. 3a), but it differs from that in having a cardinal area in both valves that has not been merged into the internal cardinal area.

FORMATION AND LOCALITY.—Middle Cambrian: (30n and 30n')^a About 3,750 feet (1,143 m.) above the Lower Cambrian and 650 feet (198 m.) below the Upper Cambrian in the shaly limestones forming 1c of the Weeks limestone [Walcott, 1908f, p. 175]; and (30o) about 3,950 feet (1,204 m.) above the Lower Cambrian and 450 feet (137.2 m.) below the Upper Cambrian in the shaly limestones forming 1b of the Weeks limestone [Walcott, 1908f, p. 178]; both on the north side of Weeks Canyon, about 4 miles (6.4 km.) south of Marjum Pass, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.

LINGULOBOLUS Matthew,^b subgenus of OBOLUS.

[Lingula and Obolus.]

Lingulobolus MATTHEW, 1895, Trans. Roy. Soc. Canada for 1895, 2d ser., vol. 1, pp. 260–261. (Described and discussed as a new genus.)

Sphaerobolus MATTHEW, 1895, idem, p. 263. (Described and discussed as a provisional new genus.)

Obolus (Lingulobolus) (Matthew), WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 683. (Characterized as a subgenus.)

Obolus (Lingulobolus) (Matthew), WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 144. (Classification of subgenus.)

Differs from typical *Obolus* in the strongly arched and thick valves, and the surface marked by subimbricated, wavy, concentric lines and striae of growth.

^a 30n is the type locality.

^b The synonymy for this subgenus does not give a complete record of the various genera under which the species now included in *Lingulobolus* were formerly placed; it gives only those references in which the genus is discussed or described. To complete the record the following mere generic references are listed:

Lingulella? Billings [1872b, p. 468; 1874, p. 67; 1882, p. 15].
Lingulepis Walcott [1889a, p. 381].

Obolus (Lingulobolus) Walcott [1898b, p. 327].
Lingulobolus Grabau [1900, p. 621].
Sphaerobolus Grabau [1900, p. 622].

Two species from the Lower Ordovician may be referred to *Lingulobolus*, namely, *O. (L.) affinis* and *O. (L.) spissus*.

The thickening of the shell mentioned by Matthew is a common feature in *Obolus*, and I do not find the arrangement of the muscle scars to vary materially from those of *O. apollinis*.
Type.—*Lingulella? affinis* Billings.

OBOLUS (LINGULOBOLUS) AFFINIS (Billings).

Obolus (Lingulobolus) affinis (Billings), WALCOTT, 1898, Am. Jour. Sci., 4th ser., vol. 6, p. 327. (New locality mentioned.)
Lingulobolus affinis (Billings), GRABAU, 1900, Occas. Papers Boston Soc. Nat. Hist., No. 4, vol. 1, pt. 3, pp. 621-622. (Described.)

General form subtriangular, with the ventral valve subacuminate and the dorsal valve slightly rounded at the beak. There is a little variation in the outline of the valves, some being slightly longer in proportion to the width. The valves are strongly convex, the dorsal being the most so. A dorsal valve 30 mm. in length has a convexity of 5 mm.; a ventral valve of the same length has a convexity of 4 mm. above the plane of the margin.

The surface of the shell is marked by fine radiating striæ and concentric lines of growth, and very fine, concentric, slightly undulating, imbricating striæ; when the outer surface of the shell is exfoliated the surface of the inner layers shows rounded, radiating striæ crossed by the concentric lines of growth, and fine, slightly irregular, concentric striæ. The interior surface over the visceral cavity is marked by minute pits or punctæ that in the anterior portion of the shell are arranged in concentric lines, giving a highly ornamental appearance to the shell when examined by a strong lens.

The shell is thick, being built up of a thin outer layer and numerous inner layers or lamellæ that are oblique to the outer surface over the anterior and lateral portions of the shell. There is a strong development of the inner layers of the shell over the visceral area, the impressions of the muscle scars and vascular markings showing on the various layers as though there had been a rapid deposit of shell substance beneath those parts. Usually the direct point of attachment of the muscle is deeply impressed in the shell substance, but not always so.

The longest ventral valve in the collection has a length of 30 mm.; width, 25 mm. A large dorsal valve has a length of 32 mm. and a width of 29 mm.

The interior casts show that the area of the ventral valve is not very clearly defined; it is rather long and divided midway by a cast of a rather narrow pedicle groove; it is very rarely that any traces of the area can be observed. The area of the ventral valve is obscure in most specimens; one example shows that it forms a shelf, the undercut projecting slightly beneath it so as to form in the cast two rounded projections extending toward the beak, on each side of the median line, giving very much the same appearance as the same parts in the dorsal valve of *Lingulella granvillensis* (Walcott) (Pl. XXII, fig. 1d).

The cast of the visceral cavity of the ventral valve is very much like that of *Obolus matinalis* (Hall) and *Obolus (Westonia) rogersi* (Walcott). The material is somewhat imperfect, but there is an outline of the heart-shaped cavity (x), and the position of the space including the central, middle lateral, and outside lateral muscle scars is indicated (Pl. XXII, figs. 1, 1b).

The muscle scars are not so well shown in this species as in the associated *Obolus* (*Lingulobolus*) *spissus*. In the ventral valve the anterior lateral and transmedian scars are so closely united with each other that they can not be differentiated. It is the same with the centrals, which appear to be crowded in with the middle and outside laterals. In the dorsal valve the central and anterior lateral muscle scars are clearly defined, and the position of the transmedian and the outside and middle laterals is fairly well shown in one specimen. The markings left on the shell by the vascular system are confined to the main or trunk sinuses, which are imperfectly represented.

Observations.—Billings [1872b, fig. 4] illustrated an elongate form of the ventral valve, and Matthew [1895b, Pl. I] a shorter ventral valve, and with it, as the dorsal valve, the dorsal valve of *O. (L.) spissus*. The form that Matthew [1895b, p. 262] has described as the variety *cuneata* is probably a dorsal valve of *O. (L.) affinis*.

This is one of the largest shells that has been referred either to *Obolus* or its subgenera. In form it resembles other cuneate species, but it differs from all in the thickness of the shell and the slight definition of the cardinal areas of the valves. It is quite probable that if we had a series representing the stages of growth the young shells would be referred to *Lingulella*, as *Lingulobolus* to me appears to be an extravagant development of a species of *Lingulella* that has had unusually favorable conditions for growth. *Obolus* (*Lingulobolus*) *affinis* is associated with *O. (L.) spissus* (Billings) and *Obolus* (*Westonia*) *rogersi* (Walcott).

FORMATION AND LOCALITY.—Lower Ordovician: (114b)^a Sandstone 1 mile (1.6 km.) north of Lance Cove, Great Belle Island, Conception Bay, Newfoundland.

(326a [Grabau, 1900, p. 613]) Limestone pebbles in a Carboniferous conglomerate north of Fall River, Bristol County, Massachusetts.

Obolus (Lingulobolus) spissus (Billings), WALCOTT, 1898, Am. Jour. Sci., 4th ser., vol. 6, p. 327. (New locality mentioned.)

Sphærobolus spissus (Billings), GRABAU, 1900, Occas. Papers Boston Soc. Nat. Hist., No. 4, vol. 1, pt. 3, pp. 622-623. (Described.)

General form ovate, with the ventral valve broadly subacuminate and the dorsal valve obtusely rounded; valves strongly convex, the dorsal being about one-third more so than the ventral. The proportions of the convexity are shown by the outlines accompanying the figures. The surface of the shell is marked by concentric lines of growth and very fine undulating, sub-imbricated, concentric striæ and very fine radiating striæ, which, crossing the fine concentric striæ, cut the surface up into minute squares or parallelograms. This type of surface ornamentation also occurs on one or two of the inner layers of the shell just beneath the outer layer. The surface of the inner layers, especially that of the lamellæ forming the anterior lateral thickenings of the shell, is marked by numerous flattened striæ and over the central portions by raised, threadlike striæ; the interior of the shell and some of the interior layers are marked by fine pits or punctæ, arranged in more or less concentric lines. In addition, there is a finely punctate surface that can be seen only with the aid of a high magnifying power.

The shell is formed of a thin outer layer and numerous inner layers or lamellæ, the latter, as oblique lamellæ, becoming more numerous over the anterior and lateral portions of the

^a 114b is the type locality, though the specimens in the United States National Museum to which that number is assigned were collected much later than the type specimens.

shell. Over the central portion of a ventral valve 13 distinct layers may be counted, and at the anterior edge of the same shell 15 of the oblique lamellæ that are strongly marked by the radiating striæ. The valves vary somewhat in size, outline, and degree of convexity. An unusually acuminate ventral valve has a length of 20 mm. and a width of 19 mm. A dorsal valve 15 mm. in length has a width of 16 mm.

Casts of the interior of the ventral valve show a rather narrow area and a strong pedicle furrow which is broad at the base. The striæ of growth on the area are arranged in an imbricated manner, very much as on the area of *Obolus prindlei* (Walcott). The area of the dorsal valve is narrow and almost concealed beneath the slightly overarched posterior margin.

The cast of the ventral valve (v) shows roughly the heart-shaped cavity (x) of *Obolus* (Pl. XVI, fig. 2k). There are no traces of a median septum in the ventral valve; in the dorsal valve the septum extends as a low ridge with a sharp crest between the central muscle scars and forward, so as to divide the anterior lateral scars.

The muscle scars are finely shown in both valves. The umbonal scar of the ventral valve is divided, as in *Obolus*, the pedicle scar being situated between the two parts. In the dorsal valve the umbonal scar is very close to the area and arches slightly backward. The scars of the central muscles are not clearly defined in the ventral valve, owing to their being crowded in with the scars of the central and outside laterals. Their position, judging from the location of the centrals in *Obolus*, is within the transversely trapezoidal area (c), indicated in Plate XVI, figure 2j. On the dorsal valve the centrals are large and distinctly defined on many casts of the interior of the shell and on partly exfoliated specimens. They are situated near the center or sometimes a short distance in advance of the center of the shell, on either side of the median ridge; they are oval in outline, the longer axis diverging slightly outward anteriorly. The anterior laterals (j) are clearly defined in both valves. In the ventral valve they are very close to the transmedian, if not actually in contact with them (Pl. XVI, fig. 2k); in the dorsal they are small and situated on either side of the median ridge a short distance in advance of the central scars (Pl. XVI, fig. 2h). The middle and outside lateral scars on the ventral valve are situated in the trapezoidal area (c), but neither is clearly separable in any specimen of the collection, unless it be in that represented by Plate XVI, figure 2k, where the outside lateral scars (l) and the middle lateral scars (k) may be present. In the dorsal valve of *Obolus*, the middle (k) and the outside (l) laterals are closely united, and they are apparently combined in an elongate scar at (l) (Pl. XVI, figs. 2a and 2g). This scar corresponds in position with the two scars in *Obolus* and it is deeply impressed in the thick shell of this species, much more so than the large central scars, which apparently were but slightly impressed or else were situated upon elevations on the inner surface of the shell. Some specimens show the elevation and others the depression for the same set of scars. The transmedian scars (i) are not so distinctly shown on most of the specimens of the dorsal valve, as they appear to have been lost in connection with the deep depression formed by the outside and middle laterals. In one specimen, however, (Pl. XVI, fig. 2a) they are fairly well defined. In the ventral valve they are closely united with the anterior laterals (j), but can be distinguished from them.

The markings left on the shell by the vascular system are well preserved in a few casts of the interior of the valve. The main or trunk sinuses are strong and curved inward a short distance in front of the visceral cavity. Numerous fine peripheral branches radiate toward the margin and a few short lateral branches toward the visceral cavity. In a dorsal valve the main sinuses curve in front of the visceral cavity, very much as in the ventral valve. The interior lateral sinuses radiate from the main sinus in toward the visceral cavity, and the peripheral branches extend upward toward the margins. In some specimens where the projections of the visceral cavity back of the central muscle scars unite with the main sinus there is an apparent broadening of the sinus that produces a rather sharp angle opposite the central scars. In the ventral valve the depressed space in front of the visceral cavity is marked by narrow, radiating, and longitudinal spaces, which apparently were occupied by the anterior portion of the viscera, as the narrow canals unite toward the heart-shaped cavity and the

areas occupied by the muscle scars (Pl. XVI, fig. 2j). This latter character is probably what Mickwitz [1896, p. 69] describes as the longitudinal striation of the area in advance of the visceral cavity in *Obolus*. The parietal scar is distinctly shown in advance of the visceral area of the dorsal valve, where its course may be followed from the median line in front of the anterior lateral muscle scars to the outward curve to the main vascular sinuses, beyond which it has not been observed. In none of the specimens of the ventral valve can the exact position of the parietal scar be determined.

Observations.—The study of the material which I collected at the typical locality in 1888 shows clearly that this species is very closely related to *Obolus*. It differs in having a smaller area and somewhat in the form and convexity of the valves. There are no special characters that do not apparently fall well within the limits of *Obolus*. There is certainly not more than a subgeneric difference between the different forms of *Obolus* and *Obolus (Lingulobolus) spissus*.

Billings [1872b, p. 467] figured a ventral and a dorsal valve, but furnished a very inadequate illustration and description. Matthew [1895b, Pl. I] illustrated what appear to be two dorsal valves, one somewhat more elongate than the other. With a large series of specimens I am unable to find any ventral valve which shows the characters illustrated by Matthew in his figure 5a [1895b, Pl. I]. On the contrary, most of them are to be observed in specimens of the dorsal valve.

FORMATION AND LOCALITY.—Lower Ordovician: (114b)^a Sandstone 1 mile (1.6 km.) north of Lance Cove, Great Belle Island, Conception Bay, Newfoundland.

(326a [Grabau, 1900, p. 613]) Limestone pebbles in a Carboniferous conglomerate north of Fall River, Bristol County, Massachusetts.

MICKWITZELLA Walcott,^b subgenus of OBOLUS.

Aulonotreta KUTORGA (in part), 1848, Verhandl. Russ.-kais. min. Gesell. St. Petersburg for 1847, No. 12, pp. 278–279. (Described and discussed in German as a new genus. The species referred to the genus belong with *Obolus*, *Obolus (Acritis)*, and *Obolus (Mickwitzella)*.)

Obolus EICHWALD, DAVIDSON (in part), 1853, British Fossil Brachiopoda, vol. 1, introduction, No. 3, pp. 135–136. (Described and discussed. As far as they have been identified in this monograph the species referred to the genus belong with *Obolus*, *Obolus (Acritis)*, and *Obolus (Mickwitzella)*.)

Not *Thysanota* ALBERS, 1860, p. 63. (Proposed for a genus of the Gastropoda; see Marshall's Nomenclator Zoologicus, p. 142.)

Obolus EICHWALD (in part), 1860, Lethæa rossica, ancienne période, vol. 1, sec. 2, pp. 924–925. (Described in French. The species referred to the genus belong with *Obolus*, *Obolus (Acritis)*, and *Obolus (Mickwitzella)*.)

Obolus (Thysanotus) MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Petersbourg, 8th ser., vol. 4, No. 2, pp. 194–195. (Characterized in German as a new subgenus. See below for translation.)

Obolus (Thysanotus) MICKWITZ, WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 683. (Characterized.)

Obolus (Mickwitzella) WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 70. (Copies the original description of Mickwitz, as below.)

Obolus (Mickwitzella) WALCOTT, 1908, idem, vol. 53, No. 4, Pl. XI, and pp. 142 and 144. (Classification of genus.)

The original description by Mickwitz follows:

The subgenus *Thysanotus*, containing a single species, *O. siluricus* Eichwald, differs from the Cambrian subgenera *Euobolus* and *Schmidtia* mainly by the fringed anterior border of the growth lamellæ of its valves, and by the concentric striation arranged parallel to the posterior edge of these lamellæ—two features that point to a peculiar organization of the edge of the mantle. The last-mentioned peculiarity appears also in the subgenus *Acritis*.

Type.—*Obolus siluricus* Eichwald.

The subgeneric name was given in honor of the late Dr. A. Mickwitz, of Reval, Esthonia.

OBOLUS (MICKWITZELLA) SILURICUS (Eichwald).

- Obolus* (*Thysanotos*) *siluricus* (Eichwald), MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 195–199, Pl. III, figs. 1–9. (Described and discussed in German; see below for translation. Fig. 9 is copied in this monograph, Pl. XV, fig. 1b.)

Mickwitz [1896, pp. 195–199] describes the species as follows:

Shells large, very flatly arched, thin, brittle. Outline of shells round, somewhat broadened. Posterior borders of shells rectilinear, not winged. Tip of the beak of large shell slightly curved inwardly. Surface of shell very lustrous, like varnish. Concentric striæ in sharp-edged ribs, which are separated by flat troughs. These ribs run parallel to the posterior borders of the growth lamellæ and therefore always become shorter toward the anterior borders of the same. Growth lamellæ prettily fringed at the anterior borders; the concentric striæ are continued on the fringes. Area large, quite smoothly striate, slightly excavated at the base of the splanchnocœlic part. Pleurocœlic part of the area extends far into the lateral borders of the shell. Traces of the pseudo-area lamellæ approach the borders of the peduncular groove, and converge into the tip of the beak. Peduncular groove large, deep, roundly hollowed, inwardly strongly broadened. Thickening of the shells very slight. Central groove of the large shell indefinitely flat. Corneous processes and sinus of the small shell strongly receding. Median swelling of the small shell broad and flat, divided at its anterior half by a broad median groove. Principal vascular traces broad and flat, separated by a median swelling into two sharp-cut furrows. Places of attachment of the central muscles of the small shell large, circular; those of the umbonal muscles very coarsely longitudinally striate.

Observations: The large shell of this species reminds one in form of *O. apollinis quenstedti*, especially of a specimen whose relative numbers also somewhat correspond with those of *O. siluricus*. In comparing these numbers, one must take into consideration that the only large shell of the last-mentioned species, which allowed measurement, is somewhat pressed in from above, so that the heights given in the table of measures may most likely be somewhat too small. The small shell, however, has a somewhat broader form than the corresponding Cambrian species, and varies in outline by having the greatest breadth nearer the anterior border.

The exterior surface of the shell of *O. siluricus* has already been spoken of on several occasions: The crescent-shaped growth lamellæ, which correspond to a vegetative period, run out as in all *Obolus* shells into the posterior borders of the shell, which, so to say, inclose them. The law of growth of the growth lamellæ, or the seam of the mantle which produces the same, is plainly here and there the same. Now the aberrancy of this species consists in the fact that the concentric striæ of these lamellæ do not converge into the tip of the crescent as the other species—with the exception of *O. antiquissimus*—but run parallel to the posterior (interior) border of the lamellæ and therefore always become shorter toward the anterior. It is self-evident that this aberrant plaited formation must have corresponded to an aberrant character of the seam of the mantle, but what the character of the latter was is unknown. Also the profile of the concentric striation of *O. siluricus* deviates essentially from the other ornamented species of Eichwald's genus; for example, *O. triangularis* shows a regular wavy line in which the crests and troughs of the wave are composed of equal curves. In *O. siluricus*, however, the curves of the troughs follow immediately on one another, so that the crests run out into sharp points. *O. antiquissimus*, which has an intermediate form, shows the crests of the waves somewhat rounded off at the point.

The fringes, with which the growth lamellæ are ornamented at the close of the vegetative period, correspond with the radial striation on the interior side of the appertaining lamellæ in such a manner that every notch between two teeth of fringes is equal to a radial furrow. These radial furrows, which owe their formation to the setæ, which are sunk into the seam of the mantle, are peculiar to all *Oboli* and were already observed in the impression by Eichwald in all shells whose upper layer (growth lamella) was broken off. To every notch of the fringe therefore corresponds a seta of the mantle. The subject can not be followed any further. We also here meet with the peculiar but unknown character of the seam of the mantle, which produces a pretty fringe in the vegetative rest; in the period of growth, however, it produces a lamella which is interrupted at the border, both being furnished with concentric ribs. The teeth of the

fringes, at the anterior border of the adult shell, reach a considerable length (four to five transverse ribs); near the beak they are only indicated.

The breadth of the growth lamellæ of this species varies greatly. One shows in the center of the shell a width of 5.5 mm., while the center lamella of another is only 2 mm. broad. This is plainly connected with the relative conditions of nourishment. Independent thereof also here, as with all *Obolus* species, a diminishing of the breadth of the lamellæ toward the anterior border of the adult shell takes place.

The shells of *O. siluricus* are very thin, and consequently the development of the inner characters is very slightly pronounced. In striking contrast to this peculiarity stands the strongly developed area with the broad, deeply hollowed peduncular groove, which somewhat diminishes toward the beak.

The surface of the area is smooth at the posterior part, and gives rise to the conjecture that in consequence of a narrow closing of the shell a mutual attrition has taken place. (Similarly as in *O. antiquissimus*, only in a less degree.) The same conclusion is forced upon one by the deeply hollowed peduncular groove, which allowed, even with the narrow closing of the shell, sufficient space for the passing of the peduncle; and lastly, the strongly developed longitudinally striate places of attachment of the umbonal muscle. A small shell of a young specimen also shows this place of attachment distinctly but lacks the striation in the figure.

The beak of the small shell also has in its youth a rectilinear bordered tip. In age this is somewhat worn off, so that the beak has a round appearance. The area of the small shell is hollowed transversely to the median line and therefore not exposed to attrition, which is limited to the borders of this shell. Unfortunately this part is only at hand in the already mentioned young specimen.

The inner characters of *O. siluricus* are more withdrawn from observation. On the one hand they are, as already mentioned, very slightly developed; on the other hand sufficient material is lacking. The central groove of the large shell is very flat and indefinitely bordered, but is perceptible in both figured specimens.

The principal vascular furrows are more distinctly distinguishable, their central swellings are strongly developed and rear themselves from the deeply hollowed lateral furrows. In one specimen the secondary vascular traces may be followed under a magnifying glass. The accessory vessels, radiating inwardly and perpendicularly to the principal vessels, run rectilinearly to the anterior border, and bend off shortly before reaching the median line, as has been demonstrated in other species. A shortly branched ramification of the first part of these vessels was only suggestively perceptible. The outwardly directed accessory vessels run in the known manner. Their opening into the peripheral canal is not perceptible on account of corrosion of this part of the shell.

Of the remaining visible characters in the figured large shell only the places of attachment of the combined central muscles are to be mentioned, which, however, can not be analyzed into their elements on account of the deficient preservation of the shell. In their totality, they form a narrow band, which lies before the central groove and is bordered by the parietal band. This band curves, close to the inner lateral furrows of the principal vessels, rectangularly toward the back and is widened there considerably. This portion, however, is corroded, so that the exact form of the place of attachment can not be ascertained.

In the small shell, apart from the already mentioned place of attachment of the umbonal muscle, the large circular places of attachment of the central muscles may be seen for the first time, and lie near the center of the fragment of the shell on both sides of the flat median swelling, which is divided by a broad median furrow. The places of attachment of the anterior lateral muscles are also perceptible, but only suggestively. They already lie in the scaled-off part of the anterior half of the shell. On the left above, the elongate, quite deeply sunk place of attachment of the transmedian muscle is also perceptible. Lastly, the beginnings of the principal vascular traces and parietal band, as far as the inner surface of the shell is intact, may be followed and are also expressed in the figure.

The species owes its specific name to the "Silurian" age of the beds in which it is found.

FORMATION AND LOCALITY.^a—Passage beds between the Upper Cambrian and the Ordovician: "Glauconite sandstone" at the following localities: (396) At Baltischport, 30 miles (48 km.) west of Reval; (396a) at *Leppiko, near Leetz, on the eastern side of the Baltischport Peninsula, about 25 miles (40.3 km.) west of Reval*; (396b) at Fall, 15 miles (24 km.) west of Reval; (396c) at the mouth of Fählna Brook, east of Fall, about 15 miles (24 km.) west of Reval; and (396e) in the eastern part of the east Baltic region; all [Mickwitz, 1896, p. 198] in the Government of Esthonia, Russia.

(395x [Lamansky, 1901, p. 617]) Glauconitic sandstone (correlated by Lamansky with the Upper Cambrian *Ceratomyge* slate) in the vicinity of Baltischport, 30 miles (48 km.) west of Reval; (395v [Eichwald, 1843, p. 147]) sandstone on Odensholm Island, about 55 miles (88.6 km.) west of Reval; (396y [Eichwald, 1843, p. 147]) chlorite-bearing sands in the limestone beds at Reval; (336f [Eichwald, 1860, p. 927]) pyroxene-bearing sands in the *Orthoceratite* limestone beds at Reval; (337i [Schmidt, 1861, p. 218]) green sand at Baltischport; and (396x [Eichwald, 1843, p. 146]) chlorite-bearing sands in the limestone beds at Baltischport, about 30 miles (48 km.) west of Reval; all in the Government of Esthonia, Russia.

(395w [Eichwald, 1843, p. 147]) Chlorite-bearing sands in the limestone beds at Pawlowsk; and (395y [Kutorga, 1848, p. 281]) sandstone on Pulkowa Brook; both near St. Petersburg, Russia.

(368a [Siemiradzki, 1886, p. 672]) Gray sandstone of unknown stratigraphic position or age, in the Polnischen Mittelgebirge, north of Sandomierz on the Vistula, Russian Poland.

^a Localities 396 and 396a are represented in the collections of the United States National Museum.

ACRITIS Volborth,^a subgenus of OBOLUS.

[ἀσπετος, indiscernible.]

- Aulonotreta* KUTORGA (in part), 1848, Verhandl. Russ.-kais. min. Gesell. St. Petersburg for 1847, No. 12, pp. 278-279. (Described and discussed in German as a new genus. The species referred to the genus belong with *Obolus*, *Obolus* (*Acritis*), and *Obolus* (*Mickwitzella*.)
- Aulonotreta* Kutorga, MORRIS, 1849, Annals and Mag. Nat. Hist., 2d ser., vol. 4, pp. 316-317. (Characterized and discussed as a synonym of *Obolus*.)
- Obolus* Eichwald, DAVIDSON (in part), 1853, British Fossil Brachiopoda, vol. 1, introduction, No. 3, pp. 135-136. (Described and discussed. As far as they have been identified in this monograph the species referred to the genus belong with *Obolus*, *Obolus* (*Acritis*), and *Obolus* (*Mickwitzella*.)
- Obolus* EICHWALD (in part), 1860, Lethæa rossica, ancienne période, vol. 1, sec. 2, pp. 924-925. (Described in French. The species referred to the genus belong with *Obolus*, *Obolus* (*Acritis*), and *Obolus* (*Mickwitzella*.)
- Acritis* VOLBORTH, 1869, Verhandl. Russ.-kais. min. Gesell. St. Petersburg, 2d ser., Bd. 4, pp. 212-217. (The description and discussion of the genus (in German) is incorporated with that of *Obolus* (*Acritis antiquissimus*.)
- Acritis* Volborth, DALL, 1877, Bull. U. S. Nat. Mus. No. 8, p. 11. (Placed as a synonym of *Aulonotreta*.)
- Aulonotreta* Kutorga, DALL, 1877, idem, p. 16. (Priority of this generic name over *Acritis* discussed.)
- Acritis* Volborth, OEHLERT, 1887, Manuel de conchyliologie, by Fischer, p. 1264. (Described in French.)
- Aulonotreta* Kutorga, HALL and CLARKE (in part), 1892, Eleventh Ann. Rept. State Geologist New York for 1891, pp. 243-244. (Described and discussed. As discussed the genus includes species referred to both *Obolus* and *Obolus* (*Acritis*.)
- Aulonotreta* Kutorga, HALL and CLARKE (in part), 1892, Forty-fifth Ann. Rept. New York State Museum for 1891, pp. 559-560. (Copy of preceding reference.)
- Aulonotreta* Kutorga, HALL and CLARKE (in part), 1892, Nat. Hist. New York, Paleontology, vol. 8, pt. 1, p. 82. (Described and discussed and priority, etc., of generic references discussed. As discussed, the genus includes species referred to both *Obolus* and *Obolus* (*Acritis*.)
- Obolus* (*Acritis*) (Volborth), MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 205-206. (Characterized and discussed in German as a subgenus; see below for translation.)
- Obolus* (*Acritis*) (Volborth), WALCOTT, 1901, Prec. U. S. Nat. Mus., vol. 23, p. 683. (Characterized.)
- Obolus* (*Acritis*) Volborth, WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 144. (Classification of subgenus.)

Mickwitz describes the subgenus as follows:

The subgenus *Acritis*, like the two preceding subgenera, *Thysanotos* (= *Mickwitzella*) and *Leptembolon*, is based on a single species, *Obolus antiquissimus* Eichwald, which, out of all the species of Eichwald's genus, departs most widely from the typical species.

The most prominent characteristics of this subgenus—apart from the parallelism of the concentric striation of the surface of the shell, which it has in common with the subgenus *Thysanotos* (= *Mickwitzella*)—consist in the remarkable shortening of the splanchnocœle, which even in the adult stage of the animal advances but little toward the frontal edge, and in the different arrangement of the deposit of the thickened lamellæ, which impart to the adult shells a totally different appearance.

The failure to recognize these facts was the main cause of the long controversy over the genus of *O. antiquissimus*, which after all threw no light on the subject.

Type.—*Obolus* (*Lucina*) *antiquissimus* Eichwald [1843, p. 142].

OBOLUS (ACRITIS) ANTIQUISSIMUS (Eichwald).

Plate XIII, figure 3; Plate XV, figures 2, 2a-d.

- Obolus* (*Lucina*) *antiquissimus* EICHWALD, 1843, Beiträge zur Kenntniss des russischen Reiches, Bd. 8, No. 2, pp. 142-144, Pl. IV, figs. 1a-c. (Described and discussed in German as a new species.)
- Obolus apollinis* Eichwald, DE VERNEUIL (in part), 1845, Géologie de la Russie d'Europe, by Murchison, de Verneuil, and de Keyserling, vol. 2, pt. 3, pp. 290-292. (Described and discussed in French. The reference includes *Obolus* (*Mickwitzella*) *siluricus*, *Obolus* (*Acritis*) *antiquissimus*, *Obolus apollinis*, and *Obolus apollinis ingricus*, *Obolus apollinis* being figured.)
- Aulonotreta sculpta* KUTORGA, 1848, Verhandl. Russ.-kais. min. Gesell. St. Petersburg for 1847, No. 12, pp. 282-283 Pl. VII, figs. 11a-d. (Described and discussed in German as a new species.)
- Obolus apollinis* Eichwald, DAVIDSON (in part), 1853, British Fossil Brachiopoda, vol. 1, Introduction, No. 3, Pl. IX, fig. 285 (not figs. 280-284, which represent *Obolus apollinis*). (No text reference. Fig. 285 is copied from Kutorga's figure, 1848, Pl. VII, fig. 11b, of *Aulonotreta sculpta*.)

^a The synonymy for this subgenus does not give a complete record of the various genera under which the species now included in *Acritis* were formerly placed; it gives only those references in which the genus is discussed or described. To complete the record, the following mere generic references are listed:

Obolus (*Lucina*) Eichwald [1843, p. 142].

Obolus de Verneuil [1845, p. 290].

Obolus Eichwald [1859, Pl. XXXVII, figs. 5a-d].

- Obolus (Acritis) antiquissimus* (Eichwald), MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 206-213, Pl. III, figs. 20-22, 24-29. (Described and discussed in German; see below for translation. Figs. 20a-b are copied in this monograph, Pl. XV, fig. 2d.)
- Obolus (Acritis) antiquissimus ventrosus* MICKWITZ, 1896, idem, pp. 213-214, Pl. III, figs. 23a-b. (Characterized in German as a new variety.)

Mickwitz [1896, pp. 206-213] describes this species as follows:

Shells large, strongly arched. Arching of the large shell slighter than that of the smaller. Greatest height of both shells more toward the beak. Outline of shell broadly oval to round, broader than long, the greatest width lying more to the anterior border. Beak of the large shell very blunt, laterally rounded; extreme tip of the beak of the large shell lapping hook-shaped over the rectilinearly worn-off tip of the beak of the small shell. Growth lamellæ very thick, loosely disposed, their anterior sharp-edged borders projecting like a molding on their inner surfaces, strongly radially ribbed. Concentric striae of the outer surface of the shell in wavy roundish ribs, which run parallel to the posterior border of the crescent-shaped growth lamellæ, growing constantly shorter toward the anterior border of the same. Anterior and lateral borders sharp-edged, lying in one plane with the worn-off borders of the beak. Posterior borders of the shell massive, broad, projecting inwardly in shape of a border. Area of both shells strongly developed, broadly ribbon-shaped, prolonged far into the lateral borders, deeply hollowed, polished on the surface by mutual attrition. Peduncular groove strongly conical, deeply sunk, inwardly often broadened like a trumpet, traces of the pseudo-area rectilinear, converging into the tip of the beak, attaining to distinctness as a line of the markation of the narrow splanchnocœlic and the broad pleurocœlic heads of the layers of the worn area lamellæ. Thickening of the shell extended chiefly to the brachiocœle, advancing in scalariformed terraces which follow the contours of the parietal band; with the large shell forming a thick mass in front of the central groove, and with the small filling out the lateral angular seams which penetrate into the splanchnocœle.

Splanchnocœle small, crowded back strongly to the beak, reaching under the rimlike projecting posterior border of the shell. Heart-shaped groove very small, very indistinctly pronounced, often only perceptible in a slightly expressed furrow between the combined central places of attachment—the projecting tip of the central groove. Median swelling of the small shell beginning as a distinctly developed roundish ridge under the hollowed area, between the places of attachment of the central muscles, which are there situated, and ending with a fine short furrow between the places of attachment of the anterior lateral muscles, which are also moved very far back. Principal vessel furrows of both shells deeply sunk, hollowed into plainly round or flat furrows; in the large shell more approximated to the median line and running rather straight; in the small shell more approximated to the lateral borders. Secondary vessels not ramified, radiating inwardly and outwardly perpendicularly to the principal vessels.

Peduncular muscles fastened to a toothlike process, which is pushed before the opening of the peduncular groove and reaches freely into the splanchnocœle. The places of attachment of the umbonal muscle, in the large shell, on both sides of the place of attachment of the peduncular muscle on the narrow sides (perpendicular to the plane of the shell border), which stands out into the interior of the shell; in the small shell on a platform, which lies opposite to the place of attachment of the peduncular muscle and projects into the interior like a pier. Combined places of attachment of the transmedian and anterior lateral muscles with the large shells in front of the divided places of attachment of the umbonal muscles on the narrow side of the projecting rimlike border of the shell; with the small shell at the corresponding place in similar position to the places of attachment of the transmedian muscles; and in front of these the combined places of attachment of the middle and outside lateral muscles. Places of attachment of the central muscles in the large shell behind those of the outside lateral muscles, lying on both sides of the projecting

tip of the central groove. Both places of attachment narrow, long drawn out, and placed transversely to the shell. On the facing ends of the places of attachment of the outside lateral muscles and divided by the projecting tip of the central groove the small, round, quite deeply depressed places of attachment of the middle lateral muscles. Places of attachment of the central muscles in the small shell moved far into the excavated tip of the beak, lying under the platform which serves the umbonal muscle as a place of attachment; very much prolonged, divided from one another by the median swelling. Places of attachment of the anterior lateral muscles of the small shell likewise moved very far toward the posterior, lying about in the posterior third of the shell, divided by a fine furrow at the end of the swelling.

Parietal band moved away from the places of attachment in its anterior part, coursing at the border of the scalari-formed terraces of thickening.

Observations: The immature shells of this extraordinary species show unmistakably the characters of the genus *Obolus*, while these latter are not so easily distinguished in adult individuals. This is especially the case with the characters of the inner surfaces of the shell, which acquire an entirely altered appearance in consequence of the formation of the shell, which varies in age, and the altered disposition of the thickening of the shell.

The relative height of the adult shell is larger than that of the young. In the same mentioned specimens it amounts to 0:171; 0:307; 0:262. The falling off to the tip of the beak is very flat with the young shell; with the old, as a rule, perpendicular. However, essential aberrances take place with the adult individuals; some show the falling off of the beak considerably flattened.

As with all other ornamented species, the ornamentation of the outer surface of the shell is altered with the advancing age of the animal. The delicate concentric striation has no waves until the close of the first vegetative period and reminds one with its parallelism (in a strict sense) of that of *O. siluricus*. At times, however, it shows some irregularities, as the parallel uniformly curved ribs at times flow together or become disturbed. With the beginning of the second vegetative period the waves occur, which, however, are often disturbed in form, and are resolved into separate small swellings. This ornamentation Volborth has fitly named "undulate-humped." Toward the anterior border the swellings are crowded again, the waves become smoother, and the concentric ribs flatten, so that the ornamentation is almost lost close to the anterior border.

The construction of *O. antiquissimus*, in comparison with the other *Oboli*, is somewhat negligent, if we may use that term. The growth lamellæ lie very irregularly on one another and protrude very unequally with their anterior sharp borders; at the same time the coherency of the lamellæ is so loose that they fall apart at the least occasion. The irregularity of the construction of the shell is shown principally at the posterior borders, at which the lamellæ are displaced perpendicularly under one another, and on account of unequal stratification give the appearance of the leaves of an uncut book.

The individual rings of the growth lamellæ (taking the latter as a whole, not only the visible parts on the surface of the shell) are very massive with *O. antiquissimus*, and are club-shaped toward the beak, in the profile, as with other species. But while in the remaining species they at the same time become narrower (crescent-shaped) toward the beak, they here retain their breadth to the traces of the pseudo-area of the area lamellæ and then pass over (in the splanchnocœlic part of the area of the base) into a position perpendicular to the plane of the border of the shell. The breadth of the rings (surface of displacement) increases with the advancing age of the shell, independently of whether the existing vegetative period produces a thin or thick lamella. The thickness is understood as the perpendicular distance between the surfaces of separation.

According to this, the construction of the shell takes place as follows: At the anterior border the growth lamellæ are separated in ordinary manner, each one sticking halfway under the preceding one. Toward the posterior the individual rings are pushed more and more below one another until they lie perpendicularly below one another at the posterior borders of the shell. Now, as every new ring surpasses the preceding in breadth, and the splanchnocœle is nominally reduced in thickness, the rings, which lie perpendicularly upon one another, form a very massively hollowed border, similar to a rim, at the posterior borders of the shell, which is also continued even in the beak. There, however (between the traces of the pseudo-area), they are built up by the lamellæ of the splanchnocœlic part of the area, which lie in front of one another, perpendicular to the plane of the border of the shell. In the umbonal part of a small shell the described lamellæ (which lie over each other) of the posterior lateral borders, as well as the posterior border of the shell which is formed by the splanchnocœlic area lamellæ, may be seen distinctly.

A principal distinction between the construction of the shell of *O. antiquissimus* and that of the other species is not present. The strengthening of the principal part of the shell (which incloses the visceral cavity) takes place with the first named through strengthening of the outer lamellæ at the expense of the inner thickening, but with the other species through strengthening of the inner thickening at the expense of the outer lamellæ.

A noteworthy appearance, which has only been noticed with *O. antiquissimus*, deserves to be emphasized. The ring-shaped lamellæ of the anterior part of the shell consist of rock-mass (limestone), but are, as all lamellæ, clothed with a homogeneous (corneous) layer, so that it gives the impression that the individual lamellæ had been hollow and after the death of the animal had been filled with calcareous mud. It is, however, more likely that the inner layer of the canal, which is less capable of resistance, was dissolved after the death of the animal and restored by the penetrating calcareous mud.

In still greater measure than through the just described formation of the border the configuration of the inner surface of the shell becomes altered through the disposition of the lamellæ of thickening, which deviates in the age of the

animal. The large shell of a youthful specimen is not essentially distinguishable in the general arrangement of the characters from the typical species, unless stress be laid on the extraordinarily strongly shortened splanchnocœle. In one specimen a slight swelling is already noticeable, which, however, does not extend to the splanchnocœle, but, moved from the places of attachment of the muscle far to the front, lies in the brachiocœle. Another already shows the beginning of the formation of terraces in the form of two slight obliquely placed swellings, which are connected in advance growth and widen out to a surface whose border (which faces the beak and falls off perpendicularly) shows an inlet corresponding to the protruded tip of the central groove in the median line of the shell. In further growth of the shells one terrace is built upon the other, each following the other scalariformly, receding from the border of the preceding one and thus gradually forming the mass. This thickening of the shell is extended only on the central part of the shell. At both sides deep, broad furrows remain, which are retained for the principal vessels. Most likely the mass is gradually flattened toward the anterior border. Unfortunately, all specimens are injured in such a manner that nothing definite could be ascertained.

With the small shell the thickening takes place in entirely similar manner. Here the terraces are chiefly separated by the lateral angular places of the brachiocœle, which are formed by the protruding splanchnocœle and form a mass scalariformly sloping, which cuts deep into the protruding splanchnocœle. A youthful specimen of the small shell shows a strongly developed mass, which, however, was for the greater part destroyed by the treatment with dilute hydrochloric acid. This manner of preparation was chosen to lay bare the posterior parts under the deeply hollowed umbonal border, which was also satisfactorily accomplished at the expense of the strongly weathered lamellæ of thickening.

Of the characters whose development is connected with the thickening of the posterior part of the shell, as the septa, corneous processes, and heart-shaped groove, nothing is to be discovered in the adult shells of *O. antiquissimus*. In young specimens, however, the central groove is mostly distinguishable, even if it is always very small, flat, and indefinitely bordered.

The principal vessels are sunk in the small shells in the usual manner, but are not divided by a middle swelling. With the adult they run in deep furrows at both sides of the central mass. Their course can not be followed in the anterior half of the shell on account of the injured condition of the shells. The accessory vessels and the peripheral canal are only perceptible in indistinct traces. The former seem to run without branching, and perpendicularly to the principal vessels.

The places of attachment of the muscles of *O. antiquissimus* have in general the same arrangement as those of the typical species. In the latter those which lie more toward the center of the shell and toward the anterior are, however, corresponding to the disposition of the splanchnocœle, strikingly long drawn out.

The peduncular muscle and the divided umbonal muscle are attached in the young shells exactly in the same manner and at the same place on the bottom of the shell of the ventral valve as in the other species. In further growth of the shells small elevations are formed at the places of attachment. The progressing development of these elevations may be followed in a series of shells. The center one of these elevations is gradually altered through corresponding attachment of the lamellæ into a toothlike process, which reaches in front of the peduncular groove freely into the splanchnocœle and serves the peduncular muscle as a place of attachment. The places of attachment of the divided umbonal muscle have gradually moved to the rimlike border of the shell (close to the peduncular furrow), whose narrow sides are turned inward. The combined spots of attachment of the transmedian and anterior lateral muscles of the large shell undergo the same change of place.

The case is entirely similar with the places of attachment of the small shell, which lie at the base of the area, and the pleurocœle (umbonal, transmedian, outside lateral, and middle lateral muscles). They all move, in the adult individuals, into a place corresponding to their position in the youthful shell, to the narrow side of the rimlike border which surrounds the posterior part of the shell. The place of attachment of the umbonal muscle acquires, aside from this, a special broadening in the form of a pier-shaped platform, which protrudes into the inside of the shell. The pierlike construction gives this place of attachment of the umbonal muscle, which (judging by the mutual attrition of the beaks) displays a considerable strength, a special firmness.

All these places of attachment, which lie at the border of the shell, are grained like shagreen, coffee-brown colored, and covered with small, lustrous, dark-brown knots.

More important than those just described is (in comparison with the typical species) the dislocation of the places of attachment, lying in the interior of the shell. They all are, in consequence of the extraordinary shortening of the splanchnocœle of this species, pushed back so far toward the beak that (especially with the small shell) an entirely distorted figure of the typical figure is brought about. The position of the combined central places of attachment of the large shell is in this regard less striking. The latter are, to be sure, moved so near to the area that only a small triangular space is left for the central groove, but the difference between this arrangement and that with *O. celatus orbiculatus* is, however, proportionately slight. Of greater importance is the aberrancy in the opposed position of the individual spot of attachment of this complex, in which, as already often mentioned, the places of attachment of the central muscles are arranged behind those of the outside lateral muscles. The combined central places of attachment could not be demonstrated in the only adult specimen of the large shell; they are lost in the strongly developed configuration of the inner surface.

The small shell, on the other hand, presents an entirely singular view. The strongly developed places of attachment of the central muscles are, with the young shells, pushed back to the most posterior part of the splanchnocœle, and lie under the platform which serves the umbonal muscles as a place of attachment, and which covers the same.

In the first-mentioned specimen, the entire posterior part is broken off, so that the long-drawn-out elliptic places of attachment (immediately in front of the foot of the broken-off platform) are visible. The second specimen had to be figured from a front view, to make the covered places of attachment visible. Between the places of attachment of the central muscles (which in *O. antiquissimus* lie nearer one another than with the other species) the slightly developed but distinctly visible median swelling comes in and is produced in the known manner as far as between the places of attachment of the anterior lateral muscle, which are also moved considerably toward the posterior.

FORMATION AND LOCALITY.^a—Passage beds between the Upper Cambrian and the Ordovician: "Glaucinite limestone" at the following localities: (396i) At Fall, 15 miles (24 km.) west of Reval; (396d)^a at Domglint, in Reval; (396h) at Tischer, 10 miles (16 km.) west of Reval; (396j) at Nömmeweske, near Palms; (337h [Eichwald, 1860, p. 929]) *Orthoceratite* limestone near Reval; and (396o) in the entire western part of the east Baltic region; all in the Government of Esthonia, Russia.

(396k) "Glaucinite limestone" at Isvos on the Wolchow; (396z) limestone in the vicinity of Zarskoe Selo; (395w) chlorite-bearing sands in the limestone beds at Pawlowsk, near St. Petersburg; (336e) *Orthoceratite* limestone at Pulkowa, near St. Petersburg; and (396l) "glaucinite limestone" at Pulkowa, near St. Petersburg; all in the Government of St. Petersburg, Russia.

(396m) "Lower lenticular layer" of the "glaucinite limestone" at Saggad, east of Palms; (396n) white limestone between the "glaucinite limestone" proper and the sandy representatives of the "Vaginatum limestone," at Leppiko, near Leetz, on the eastern side of the Baltischport Peninsula, about 25 miles (40.3 km.) west of Reval; (396g) upper limestone at Reval; (396x) chlorite-bearing sands in the limestone beds at Baltischport, about 30 miles (48 km.) west of Reval; (396y) chlorite-bearing sands in the limestone beds at Reval; (336d) *Orthoceratite* limestone at Reval; and (396p) strata between the "lower lenticular layer" and the "Vaginatum limestone" proper, at Nömmeweske, near Palms; all in the Government of Esthonia, Russia.

(386b) Drift blocks of "glaucinite limestone" near Wehlau, 30 miles (48 km.) east of Königsberg, East Prussia, Germany.

OBOLUS (*ACRITIS?*) RUGATUS Walcott.

Plate XIII, figure 2.

Obolus (Acritis?) rugatus WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 694. (Characterized as a new species.)

The concentric surface lines which are the characteristic feature of this shell, although much coarser, are the same type as those of *O. (Acritis) antiquissimus* (Eichwald) and terminate on the posterolateral margins in much the same manner. It is a very rare form, only one specimen having been collected, although the beds in which it occurs were very thoroughly searched during the survey of the Eureka mining district. All that is known of the species is shown by the figure illustrating it. It is probably not an *Acritis* and probably not an *Obolus*. The peculiar surface, as shown in Plate XIII, figure 2, is very much like that of a Silurian species named by Clarke *Glossina acer*.^b

This form owes its specific name to the coarseness of the concentric surface lines.

FORMATION AND LOCALITY.—Middle Cambrian: (58) Shaly limestone in upper beds of Secret Canyon shale, east side of New York and Secret canyons, Eureka district [Hague, 1892, Atlas], Eureka County, Nevada.

SCHMIDTIA Volborth,^c subgenus of OBOLUS.

Schmidtia VOLBORTH, 1860; see Marshall's Nomenclator Zoologicus, p. 137.

Not *Schmidtia* BALSAMO-CRIVELLI, 1863. (Proposed for a genus of Porifera.)

Schmidtia VOLBORTH, 1869, Verhandl. Russ.-kais. min. Gesell. St. Petersburg, 2d ser., Bd. 4, pp. 208–209. (Discussed in German.)

 (Classification of genus.)

The original description by Mickwitz follows:

The subgenus *Schmidtia*, out of all the subgenera of Eichwald's genus, is most closely related to the subgenus *Euobolus*. Some species of that subgenus, especially *O. celatus* and to a less degree *O. crassus*, show in their general appearance so much resemblance to *O. apollinis* that they might pass for miniature models of it. The other two species, on the contrary, depart from the typical species in the form of the valves and in the shape of the area; *O. obtusus*, in outline and in the flatness of its valves, rather resembles *Lingula*, while *O. acuminatus* has a very peculiar form, differing from all *Oboli*, and due in part to the peculiar conformation of the apex of the beak.

The main arguments for establishing a special subgenus *Schmidtia* alongside of the subgenus *Euobolus*, aside from the extraordinary smallness of the valves, are: the absence of radial striation of the surface of the valve; the absence of longitudinal striation from the slope of the thickened posterior part of the valve, as well as of the posterior edge of the central pit; the invariably more uniform thickening of the valves, manifested in this, among other things, that the pleurocœlic parts of the valves differ in nothing from the frontal and side edges; the fact that the area of the large valve is broken in the plane of the pedicle furrow; the pit-shaped depression of the splanchnocœlic part of the area of the small valve; the pestle-shaped form of the central pit; the recession of the horn-shaped projections and of the sinus of the small valve, while the median ridge simultaneously predominates. A further difference seems to exist in the different conformation of the inward-radiating secondary vessels, which in some species of the subgenus *Schmidtia* are variously ramified, whereas in the subgenus *Euobolus*, so far as can be seen, they are more rectilinear and less branched. Still the knowledge of these organs in the species of the two subgenera is as yet too imperfect to permit a definite statement.

Type.—*Schmidtia celata* Volborth.

Observations.—The reasons stated by Mickwitz [1896, p. 158] for establishing *Schmidtia* as a subgenus of *Obolus* are essentially those that differentiate it from *Lingulella*. The species of the latter subgenus are radially striated and the shells are uniformly thinner. So far as known, all of the species of *Schmidtia* are those described by Mickwitz from the *Obolus* beds of Russia. In order to place before the student full details of the species, I have had drawings made from the original specimens received from Mickwitz, and have also introduced the greater portion of his detailed descriptions. In order also that there may be a reference in this monograph to the varieties Mickwitz has determined, these are included in the synonymy of the different species referred to *Schmidtia*.

The subgeneric name was given in honor of Dr. Fr. Schmidt, of St. Petersburg, Russia.

OBOLUS (SCHMIDTIA) ACUMINATUS Mickwitz.

Plate XIV, figures 2, 2a-c.

- Obolus* (*Schmidtia*) *acuminatus* MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Pétersbourg, 8th ser., vol. 4, No. 2, pp. 179-183, Pl. 11, figs. 39 and 40. (Described and discussed in German as a new species; see below for translation.)
Obolus (*Schmidtia*) *acuminatus alatus* MICKWITZ, 1896, idem, pp. 183-184, Pl. II, figs. 41 and 42. (Described and discussed in German as a new variety.)
Obolus (*Schmidtia*) *acuminatus humeratus* MICKWITZ, 1896, idem, pp. 184-186, Pl. II, figs. 43 and 44. (Described and discussed in German as a new variety.)
Obolus (*Schmidtia*) *acuminatus subtriangularis* MICKWITZ, 1896, idem, pp. 186-187, Pl. II, figs. 45 and 46. (Described and discussed in German as a new variety.)

The original description by Mickwitz follows:

This remarkable species comprises, as the preceding, a number of forms essentially deviating from one another (especially in outline), whose unity can be safely asserted only by the agreement of certain characters important for the distinction of different species of the subgenus *Schmidtia*. To these belong, in the first rank, the peculiarly developed beak, with the aberrantly placed indications of a pseudo-area, which stands in a certain opposition to that of *O. obtusus*. The latter shows, as we have seen, this part of the shell flat, obliquely truncated, and the traces of a pseudo-area far removed from the peduncular groove. With *O. acuminatus*, on the contrary, the beak is highly arched, inwardly bent, and the traces of a pseudo-area coincide with the borders of the peduncular groove.

Diagnosis: Shells small; large shell (ventral valve) strongly arched, small shell (dorsal valve) more weakly. Greatest height of both shells directed more toward the beak. Outline oval. Beak of the large shell high, pointed, falling off steeply toward the tip of the beak and the umbonal borders. Tip of the beak bent inward. Anterior border

of the large shell somewhat receding from the plane of the lateral borders. Beak and anterior border of the small shell somewhat projecting beyond the same. Shell borders thin, sharp edged, in the small shell formed like the border of a plate. Outer surface of the shell polished, somewhat irregular because of unequally deeply cut concentric furrows, and rough toward the front because of the projecting borders of the lamellæ. Area small, in the large shell triangular; in the small, shaped like a band. Splanchnocœlic part of the large shell reduced to the borders of the peduncular grooves; with the small excavated into narrow furrows. Pleurocœlic parts of the large shell deeply hollowed out; in both, at the base, posteriorly somewhat caudate, extended, and drawn out into the lateral borders. Peduncular groove parallel-bordered, narrowing as a rule toward the apex of the shell in the excavation of the area supported by a bridge. Traces of a pseudo-area on the large shell coinciding with the borders of the peduncular groove or running very close to the same; in the small shell in similar position, including between them the narrowly grooved, excavated, splanchnocœlic part of the area surface. Shell thickening slight. Median septum under the magnifying glass mostly perceptible, in the large shell often in connection with the bridge supporting the peduncular furrow. Lateral septa receding. Median swelling of the small shell plainly developed, between the places of attachment of the anterior lateral muscles in the form of a sharp ridge. Posterior part of the central depression very widely extended; anterior part parallel-bordered, at the tip scarcely broadened.

Observations: *O. acuminatus* is, next to *O. obtusus*, the most characteristic species of the subgenus. The most essential differences of these two species, which lie in the formation of the beak, have been referred to in the beginning. For the rest they also differ so far from each other in the form and size of their shells that a confusion of them is prevented. The external characters which separate *O. acuminatus* from the two other species of the subgenus *Schmidtia* are less striking.

From *O. celatus* the species now in question is separated externally principally through the oval outline, in the more considerable height of their shells, whose greatest height lies more toward the beak; from *O. crassus*, to which it is closely related in relation to the outline and height of the shell, through the steeper falling off of the arching toward the tip of the beak. The shells of the last-named species have likewise an oval outline, but the relative breadth of the same is greater. Also the arching of the shells in *O. crassus* is somewhat stronger in the middle, but the greatest height lies more toward the center of the shell. The S-shaped section of the border of the large shell of *O. acuminatus*, to which a slight concavity in the small shell corresponds, was also noticed in *O. celatus præcisus*; but here also the broad oval outline of the shells of this variety and the flat falling off of the arching of the tip of the beak give a certain and distinctive external character.

The relations are shown more clearly by comparing the average characters of the respective relative numbers than by figures and descriptions.

The aberrant characters, which are present in the interior of the tip of the beak, are by far more important for the distinction of the species than the external differences of form. The most characteristic among these is the position of the traces of the pseudo-area, which in *O. acuminatus* run parallel and coincide with the peduncular groove; in *O. celatus* and *O. crassus*, however, they are removed from the latter and converge posteriorly.

The form of the shells of *O. acuminatus* shows but slight deviations. In some specimens the highly arched beak of the large shell, which falls off steeply posteriorly and laterally, is somewhat more sharply pointed and the tip of the beak seems to be compressed toward the side. In others the S-shaped section of the border of the large shell is more slightly wavy, but in the differences of form no rule can be perceived. It is similar with the small shells.

In regard to regularity, however, the outer surface of the shell seems to be subject to greater deviations than the foregoing species in their concentric striations. Besides forms with entirely smooth and lustrous shell surfaces, some occur that have very irregularly deep sculptured concentric furrows, which become especially irregular toward the anterior border and give the shells a dull aspect.

The area is in both shells very unevenly striate, and in the large shells, on account of the fracture in the peduncular furrow and the somewhat incurved tip of the beak, it is, as a rule, slightly excavated. With normally built shells the traces of the pseudo-area show slight inclination to separate themselves from the borders of the peduncular furrow; and the deviations (which some specimens pointing to the variety *alatus* show in this direction) are always very small. In the small shell, whose traces of a pseudo-area lie opposite those of the large shell, these deviations show themselves in a greater breadth of the furrow similar to the peduncular groove-like furrow which forms the splanchnocœlic part of the area.

The crowding of the splanchnocœle into the beak of the large shell (which is conditioned by the high arching and the uniformly slight thickening of the same) is only a more marked form of the groove-shaped excavation of the base of the area. Shells whose beaks are more flatly arched show as a rule a more distinct thickening of the posterior part, and, in connection therewith, an unexcavated, massive tip of the beak. The same is also the case with the small shells of this species. Likewise the bridge supporting the peduncular furrow is foreshadowed in that the groove-like hollowing out of the base of the area at the mouth of the peduncular furrow is transplanted into the splanchnocœlic part.

The inner configuration of the shells is, on account of the defective thickening, as a rule slightly pronounced. An exception is formed by the spots of attachment of the central muscles of both shells and the median swelling of the small shell, which are always easily perceptible. The former are shown deeply sunken in the large shell, and in the roundish form characteristic for the *Schmidtias*, while the laterally situated places of attachment of the outside lateral muscles are only slightly deepened, but are separated from those by a distinct ridge. In a small shell the places of attachment of the central muscles appear in the form of strong protuberances. The median swelling is, in opposition to that of *O. obtusus*, at its anterior border (between the places of attachment of the anterior lateral muscles) undivided, and posteriorly united with the feeble median septum. In a large shell the latter appears as a very sharp, small ridge.

Of the remaining places of attachment of the muscles there are also plainly to be seen the ones lying in the neighborhood of the area in the small shell, while they are lost, in the large shell, in the border of the excavation.

The central depression in the large shell is always very shallow.

Of the circulatory system are to be distinguished only the posterior ends of the principal vascular canals, under the magnifying glass.

The accessory vessels and the peripheral canals, on the contrary, are so feebly developed on all the observed specimens that only indistinct traces are perceptible by reflected light.

FORMATION AND LOCALITY.—**Upper Cambrian:** *Obolus* sandstone at the following localities: (395)^a at Joa, near Jegdeleht, 12 miles (19.3 km.) east of Reval; (395a) at Tihala, near Jegdeleht; (395b) at Ilgast; (395c) at Asserien, 75 miles (121 km.) east of Reval; (395d) at Ontika, about 95 miles (153 km.) east of Reval and 30 miles (48 km.) west of Narwa; and (395e) at Isenhof, 85 miles (137 km.) east of Reval; all [Mickwitz, 1896, p. 183] in the Government of Esthonia, Russia.

The original description by Mickwitz follows:

This species was first described by Volborth, who also gave us the first knowledge of a part of the places of attachment of the muscles. The first figure of a small shell is, however, found in Pander's above-cited work as *Ungula ovata*; but this drawing lacks all internal characters with exception of the plate-shaped border of the shell, which Volborth also mentions. Much more exact drawings of a whole series of *Schmidtias* (without names or description) are preserved to us in a sheet among the papers left by Pander, which was kindly handed over to me by Professor Lahusen. The places of attachment of the muscles, especially of the small shells, are in some of these figures present in full proportion, but, to be sure, not disentangled as their individual constituent parts. Also on one specimen of a large shell are plainly designated the principal and accessory vessels (which radiate inwardly). I have not utilized these drawings in any present work, because my material is much more complete than that of Pander, and, moreover, the species described by me could not with sufficient certainty be identified with the drawings in question.

Diagnosis: Shells small, slightly arched; arching of the small shell slighter than that of the large shell. Outline of the shells roundish, umbonal border of the large shell rectilinear. Surface of shell very smooth and lustrous; concentric striation very fine, in thickness somewhat irregular. Anterior (*Stirn*) and lateral borders thin, sharp margined; those in the small shell usually somewhat thickened, with the umbonal borders lying in one plane. Area small, in the large shell slightly interrupted in the peduncular furrow; in the small shell, in the splanchnocœlic part, deepened

^a Locality 395 is represented in the collections of the United States National Museum.

into a depression; peduncular furrow shallow but plainly developed, slightly diminished toward the tip of the beak. Traces of a pseudo-area bent slightly concave to the area lamellæ at the median line of shell, converging into the tip of the beak. Shells almost uniformly thick, toward the beak only a little thickened. Traces of the principal vessels broad, shallow, little prominent; middle swelling and lateral furrows of the same scarcely projecting. Secondary, inwardly radiating vessel traces in the large shell in the principal direction perpendicular to the principal vessels; in the small one curved anteriorly, in both very indistinctly ramified. Central groove of large shell pestle-shaped, with a slight swell. Apex of central groove relatively broad, somewhat drawn out, parallel-bordered, generally somewhat involved with the combined central places of attachment of the muscles. Median swelling of small shell distinctly developed, growing over into the median septum, at times separated by a fine median groove. Corneous processes and sinus receding very much.

Observations: *O. celatus* varies as all *Obolus* species in its external form and internal configuration of its shells. The want of space, however, forbade the illustration of these alterations in a manner similar to that used for the principal species of Eichwald's genus. I had to restrict myself to the illustration of the extreme members of the series of forms. This remark concerns all species of the subgenus *Schmidtia*.

Aside from the form figured by Volborth, some with circular outline and others with flattened anterior border occur, which are connected with the principal forms by transitions and were demonstrated in their extreme members as *O. celatus orbiculatus* and *O. celatus præcisus*. To all members of this group, brought together as *O. celatus*, a noteworthy peculiarity of accessory nature is common which is lacking in the remaining species of the subgenus *Schmidtia*, and which, therefore, may be looked upon as a further argument for the conspecificity of the forms mentioned. This peculiarity is a fine netlike coating, which may be found on many of these shells and which often covers the surface of the shell in several superimposed layers in the form of crusts. It may indicate the existence of a bryozoan. Traces of the netlike coating are, however, also found in the specimens of the variety *præcisus*.

The tip of the beak and the anterior border of the large shell deviate in some specimens from the normal character in such a manner that both recede somewhat from the level of the border of the shell; then in the corresponding small shell the reverse occurs so that the closing of the shell is secured. The receding of the beak is nevertheless never so strong as, for example, in *O. obtusus*. The flat plate-shaped border [Volborth, 1869, p. 210] of the small shell is formed by the last separated lamella of the border, which is marked off from the remaining surface by the principal vessel furrows which course along its inner border, and, in consequence of the flatness of the small shell, it stands out more distinctly. In the large shell the principal vessel furrows are moved more toward the interior of the splanchnocœle, and as the shell also has a stronger arching, the lamellæ of the border recede farther. Besides, this formation, which is found in all species of the subgenus *Schmidtia*, is very variable in its strength and in some small shells hardly perceptible. On the other hand, it at times also occurs in the large shells in which the peripheral canals play the same part as the principal vessel furrows.

The surface of the area of the large shell in this species of the subgenus *Schmidtia* is least broken in the peduncular furrow, and the area itself reminds one of that of the typical species, especially in that the traces of the pseudo-area of the area lamellæ converge into the tip of the beak. The pleurocœlic parts of the area of both shells are only slightly prolonged into the lateral borders. On the other hand, the area of the small shell deviates from that of *O. apollinis* by the deepening of its splanchnocœlic part, which possesses in consequence of the special position of the traces of the pseudo-area in this species a subtriangular form.

The form of the central groove varies within rather wide limits. Through lateral restraint of the posterior part of the protruded parallel-bordered tip there results an irregular biscuit-shaped outline, and through compression of the posterior broad part of the central groove in the median direction, a simultaneous shortening and tapering of the anterior part. Some shells show the protruded tip laterally compressed, so that only a narrow groove is left, which is then as a rule inclosed by strong swellings. In others this groove possesses a breadth which almost equals the posterior part of the central groove. All these alterations of form, which seem subject to no law, are also peculiar to all other species of the subgenus.

The side septa and median septum are, even if slightly, developed in both shells. The former as a rule stand out more distinctly in the large shells; the latter, however, in the small ones, where it is more distinctly expressed, appears as a prolongation of the always strongly pronounced median swelling.

The corneous processes and the sinus of the small shell are rarely to be distinguished. Yet in some specimens, in reflected light under a lens, two fine ridges are seen, which converge from the external sides of the places of attachment of the central muscles toward the beak and, with the median swelling, form a triradiate figure.

In spite of their minuteness the places of attachment usually stand out distinctly, especially those of the central muscles, which in both shells as a rule are let down deeply with swelled borders. Also the separation of the combined places of attachment is attained with the help of a lens, although naturally with more difficulty than in the larger forms of Eichwald's genus. It is very difficult to perceive the places of attachment of the transmedian and the combined places of attachment of the outside and middle lateral muscles in the small shells. The places of attachment of the central muscles, as also those of the outside and middle lateral muscles of the large shell, have more roundish forms and are not so closely connected as in the species of the subgenus *Euobolus*. Noteworthy is also the somewhat deviating position of the places of attachment of the central and anterior lateral muscles in the small shell.

The direction of the longitudinal axes converge, in the former toward the beak, in the latter toward the anterior border. As these places of attachment have in by far the most cases a pronounced elongate form, this position is very striking and was also noticed by former observers [Volborth, 1869, p. 210].

Little is to be said of the vessels. It is the easiest, especially in the small shells, to distinguish the peripheral canals, which lie on the plate-shaped border and are usually perceptible under the lens. It is more difficult to perceive the principal vessels. They easily lose themselves in the small shell in the terrace of the plate-shaped border and are but seldom perceptible in the large shell in spite of their freer position.

The lateral vessels sink in their minuteness to microscopic sizes and are distinguishable only in exceptional cases by use of strong enlargement. This is particularly the case in the ramifications, which are very indefinite in this species. The figured specimens allow the vessel system to be perceived very faintly under the lens.

As a rule the parietal band is seen, and it is also faintly suggested in the figures. In the small shell it also stands out on account of the fine-grained character of the splanchnocœlic part of the shell.

FORMATION AND LOCALITY.^a—Upper Cambrian: *Obolus* sandstone at the following localities: (395) At Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; (395a) at Tihala, near Jegelecht; (395b) at Ilgast; (395c) at Asserien, 75 miles (121 km.) east of Reval; (395d) at Ontika, about 95 miles (153 km.) east of Reval and 30 miles (48 km.) west of Narwa; and (395e) at Isenhof, 85 miles (137 km.) east of Reval; all in the Government of Esthonia, Russia.

Obolus conglomerate at the following localities: (395g) At Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; (395h) at Tihala; (395i) at Ilgast; (395j) at Asserien, 75 miles (121 km.) east of Reval; (395k) at Ontika, about 95 miles (153 km.) east of Reval and 30 miles (48 km.) west of Narwa; (395l) at Isenhof, 85 miles (137 km.) east of Reval; all in the Government of Esthonia, Russia.

Sandstone below the *Obolus* conglomerate at the following localities: (395m) At Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; (395n) at Tihala; (395o) at Ilgast; (395p) at Asserien, 75 miles (121 km.) east of Reval; (395q) at Ontika, about 95 miles (153 km.) east of Reval and 30 miles (48 km.) west of Narwa; and (395r) at Isenhof, 85 miles (137 km.) east of Reval; all in the Government of Esthonia, Russia.

(336o) Ungulite grit at Koporje, Government of St. Petersburg; and (336p) Ungulite grit at Kunitz, Government of Pskow; both in Russia.

Schmidtia conglomerate (part of the *Obolus* conglomerate) at the following localities: (395s) At Asserien, 75 miles (121 km.) east of Reval; (395t) at Ontika, about 95 miles (153 km.) east of Reval and 30 miles (48 km.) west of Narwa; and (395u) at Isenhof, 85 miles (137 km.) east of Reval; all in the Government of Esthonia, Russia.

OBOLUS (SCHMIDTIA) CRASSUS Mickwitz.

Plate XIV, figures 4, 4a-d.

Obolus (Schmidtia) crassus MICKWITZ, 1896, Mém. Acad. imp. sci. St.-Petersbourg, 8th ser., vol. 4, No. 2, pp. 187-193, Pl. II, figs. 47-49, 52-55. (Described and discussed in German as a new species; see below for translation.)

Obolus (Schmidtia) crassus angulatus MICKWITZ, 1896, idem, pp. 193-194, Pl. II, figs. 50 and 51. (Described and discussed in German as a new variety.)

The original description by Mickwitz follows:

Obolus crassus is the most abundant species of the subgenus *Schmidtia*. Its shells are massively built and to this circumstance we are indebted for the remarkably strong development of all the internal characters, a development which has been of the greatest importance in rendering possible the determination of the organization of the genus *Obolus* Eichwald. With the large choice of well-preserved shells, specimens are found which preserve the finest detail, as, for example, the outwardly and inwardly radiating accessory vessels, the opening of the principal vessels of the large shell into the peripheral canal, etc. This development of the inner characters, standing alone among all the *Obolus* species, which, so to speak, forms the basis of the anatomical part of the present work, and in many doubtful cases has proved decisive, was the cause of directing to the shells of *O. crassus* especial attention, which finds expression in the increased number of figures and measurements.

Diagnosis: Shells small, thick. Large shell (ventral valve) strongly arched, small shell (dorsal valve) less so. Outline of shells broadly oval, umbonal borders convex. Surface of the shell faintly polished; concentric striation rather fine, not uniform. Growth lamellæ bordered by quite deeply engraved lines, toward the anterior border not strongly projecting. Shell borders massive, blunt; plate-border formation slightly developed. Anterior border and tip of the beak of the large shell mostly receding a little from the plane of the lateral border; in the small shell projecting. Area very large, triangular, unevenly striate. In the large shell somewhat broken in the peduncular groove; in the small one slightly deepened in the splanchnocœlic part; in both slightly excavated into furrows at the almost rectilinear base. Peduncular groove deeply cut, narrowing slightly toward the tip of the beak. Traces of the pseudo-area strongly developed, rectilinear, more or less converging posteriorly, separating the lateral borders.

Thickening of the shell quite regular, somewhat stronger at the splanchnocœlic part. Septa of both hardly perceptible. Corneous processes of the small shell suppressed by the strongly developed median swelling, which includes the entire protruded splanchnocœle and fills the sinus. The median swelling has a fine median furrow at the anterior border. Central groove of the large shell as a rule deeply sunken and bordered by swellings. Posterior part very broad, anterior projecting tip parallel-bordered.

^a Locality 395 is represented in the collections of the United States National Museum; the remaining localities are taken from the references given in the synonymy. The authority for each locality cited is given in the list of localities, pp. 161-291.

Principal vessel furrows broad and flat. Central swelling of same slightly pronounced. Central swelling of the peripheral canals mostly separated into square sections by furrows which are parallel, directed obliquely outward, and which subside posteriorly. Secondary inwardly radiating vessel furrows strongly and irregularly branched; in the large shell perpendicular in their principal direction to the principal vascular canals; the posterior ones running out into the interior of the brachiocele, those more anteriorly placed bending toward the peripheral canal and opening into the same. In the small shell these furrows take an oblique direction, anteriorly and internally from the lateral parts of the principal vascular canals but posteriorly and externally from the parts turned off toward the places of attachment of the anterior lateral muscles. Secondary outwardly radiating vascular traces in both shells rectilinear, perpendicular to the principal vascular furrows, plainly forked, close before the opening into the peripheral canal.

Places of attachment of the muscles in both shells strongly sunken, those of the central and outside lateral muscles of the large shell oval, somewhat separated from one another by a small swelling.

Parietal band in both shells plainly developed, normally running out, brought out through the fine-grained condition of the surface.

Observations: *O. crassus* reminds one, in the form of its shell, of *O. acuminatus* in relation to the position of the traces of the pseudo-area; it takes, on the contrary, an intermediate position between *O. celatus* and *O. obtusus*. The relations to *O. acuminatus* have already been mentioned (p. 443). Further, at the same place it was pointed out that the traces of the pseudo-area of both species (*O. crassus* and *O. celatus*) converge posteriorly. The difference in the position of the converging pseudo-areas of the two last-named species is, however, very essential and consists in the fact that in *O. celatus* the same opens into the tip of the beak; with *O. crassus*, on the contrary, the borders of the area intersect at a certain distance from the beak. The last can, under some circumstances, become so large that the traces of the pseudo-area maintain a subparallel position which reminds one of that in *O. obtusus*. A confounding of the two species in this rarely occurring case is meanwhile excluded on account of the high triangular area and the deviating form of the shell of *O. crassus*. In a majority of the shells the convergence of the traces of the pseudo-area is distinctly pronounced.

The high, coarsely striate area has a plump form in consequence of the pleurocœlic part being only slightly drawn out into the lateral borders, and on account of its convex external borders, which contrast strongly with those of *O. celatus*. Its base runs almost straight, is always composed, in common with the other species of the genus *Obolus*, of three shallow curves, and is slightly grooved; tip in the large shell usually recedes somewhat from the plane of the shell borders. The break in the surface of the area in the large shell, in the peduncular, is insignificant but somewhat stronger than in *O. celatus*; the sunken splanchnocœlic part of the area in the small shell has a trapezoidal form, in consequence of the special position of the traces of the pseudo-area, and is somewhat hollowed out in the median direction. * * *

The profile of the shell borders shows in both shells, as a rule, a straight line; in the small shell it is at times slightly bowed concavely. The shell borders themselves are, corresponding to the thick condition of the shells of this species, thicker and less sharp than with the other species of the subgenus *Schmidtia*.

The external surface of the shell possesses a rather coarse concentric striation, which becomes somewhat stronger toward the anterior border, but does not stand out in the projecting intricate form as observed in other species of the subgenus.

The character of the internal surface of the shell offers in general the same picture which we have learned to know in *O. celatus*. With the majority of the shells the central pit has the normal, pestle-shaped form, and is inclosed by a more or less pronounced swelling. One specimen shows the latter at the posterior border and on the sides of the depression swollen up. With another specimen it is, on the contrary, entirely absent and the central depression appears shallowed and indefinitely bordered. This shell is in a somewhat abnormal condition. It shows in profile an arrest of growth through which the greatest height is shoved toward the beak. At the same time it shows the places of attachment of the central muscles as thick protuberances—especially on the right side. The septa of both shells are very weakly developed, likewise the corneous processes of the small shell, which, as with all *Schmidtias*, recede before the powerfully developed median swelling. The latter is in its anterior half provided with a fine median groove.

In reference to the places of attachment of the muscles of *O. crassus* there is nothing essential to be added to the condition found in the other *Schmidtias*. They are found here in exactly the same position and condition as in the other species of the subgenus, so far as the modified form of the shells does not condition slight alterations. It is at all events to be insisted upon that these characters in the present species are found in a condition of distinctness, which the remaining species of the subgenus do not show in equal degree.

Into the circulatory system of *O. crassus*, on the contrary—which, through its prominent development and preservation, explains many conditions which, in the other species, must remain undecided—I shall enter more closely.

The principal vessels of the large shell of this species are moved somewhat nearer to the median line than in *O. celatus* and at times acquire a subparallel position. This character, nevertheless, is extremely variable and is dependent on the form of outline of the shell. Broader forms show these traces more approximated to the border of the shell. In the small shell the principal vessel furrows run in the manner known near the border of the shell and parallel to the same. The opening of the principal vascular canals of the large shell into the peripheral canal is plainly to be seen under a lens by reflected light. * * *

The peripheral canals show a peculiar formation, which hitherto has not been noticed in the other species of the subgenus *Schmidtia*. The median swelling of the peripheral canals (especially at its posterior parts) is separated by short, obliquely placed cross furrows, which anteriorly run inward, posteriorly outward, into a series of small square sections, which as a whole resemble a twisted ribbon. This character is somewhat inconstant and seems to appear

only in those shells whose characters, upon the whole, are strongly pronounced. It is self-evident that such fine particularities are only perceptible by strong magnification in reflected light; they could not be distinctly reproduced without impairing the value of the figures.

The secondary vessels, which radiate inwardly, vary essentially both in their course and in the manner of their ramification. In the large shell, as a rule, they ramify rectilinearly and perpendicularly to the principal vessels and throw off short branches to both sides; only those which lie more anteriorly curve toward the anterior border and open between the principal vascular furrows into the peripheral canal.

The accessory vessels run out entirely different in another specimen. Here they fork shortly after branching off from the principal vessels and take their course to the posterior part of the shell. Nothing is to be seen of an opening into the peripheral canal of the anterior border. Lastly, another shell, where these organs leave the most indistinct traces, shows an irregular confusion of treelike ramified canals, the directions of which seem to alter by every turning of the shell under the lens.

The accessory vessels of the small shell, which radiate inwardly, show similar differences. As a rule, the accessory vessels issuing from the central part of the principal vessels, turn anteriorly immediately after their exit from the latter, and are slightly curved in the shape of an S and hardly ramified. Only those lying at the extreme back bend into the angular spaces of the brachiocœle, which are formed by the parietal band; the accessory vessels, however, which ramify from the anterior, inwardly bent ends of the principal vessels, run rectilinearly posteriorly. Another specimen, however, shows the central accessory vessels directed more posteriorly and very strongly ramified.

What significance these essential deviations have in the systematic aspect can not, however, be established at present. No correlation has hitherto been obtained.

The secondary outwardly radiating vascular traces correspond, in all examined specimens, in regard to their arrangement and course. Branching off perpendicularly to the principal vessels, the straight, short traces fork before opening into the peripheral canal.

As in *O. celatus*, the parietal band may be followed as a fine furrowed swelling, and where perceptible traces are lacking it is often established through the difference in the character of the surface of the splanchnocœle and brachiocœle.

This form owes its specific name to the massiveness of its shells.

FORMATION AND LOCALITY.^a—Upper Cambrian: *Obolus* sandstone at the following localities: (395) At Joa, near Jegeleht, 12 miles (19.3 km.) east of Reval; (395a) at Tihala, near Jegeleht; (395b) at Ilgast; (395c) at Asserien, 75 miles (121 km.) east of Reval; (395d) at Ontika, about 95 miles (153 km.) east of Reval and 30 miles (48 km.) west of Narwa; and (395e) at Isenhoï, 85 miles (137 km.) east of Reval; all [Mickwitz, 1896, p. 192] in the Government of Esthonia, Russia.

The original description by Mickwitz follows:

This extraordinary species, whose principal characteristics consist in the peculiar character of the area which is predominantly prolonged, consists of a large number of shells, which do not essentially deviate in outline and size. All of these forms are rare; of some of them only one was found; in consequence, their cospecificity could not be proven

^a Locality 395 is represented in the United States National Museum collections

in all cases through transitions. I was for a long time undecided as to whether I should refer all of these aberrant shells to one species. Nevertheless, the fact that deviations in a much greater measure are not extraordinary in other *Obolus* species, and, furthermore, the fear of multiplying the number of species without decisive reason, and, lastly, the correspondence of the different forms in the mentioned principal characters persuaded me to look upon the entire group as belonging to one species. The characteristic form was erected into a species and the others were subordinated to it as varieties. However, it is possible that with more complete material the one or the other variety will be removed from the species. At present this arrangement will make easy the general view of the forms.

Diagnosis: Shells moderately large, flatly arched, drawn out lengthwise. Outline subtriangular. Tip of beak of the large shell somewhat protruded, obtuse-angled, externally obliquely truncated; small shell almost rectilinearly cut off. Borders of the beak of the large shell receding from the plane of shell borders, going over into the lateral borders with a roundish angle. Exterior surface of shell very smooth, strongly lustrous like varnish, concentric striæ very fine. Growth lamellæ marked by somewhat coarser grooves, commonly standing out at the anterior border like shingles. Area large, splanchnocœlic part broad, band-shaped; pleurocœlic part prolonged far into the lateral borders. Plane of the area of the large shells broken in the peduncular groove, in the small shell depressed into broad grooves between the traces of the pseudo-area. Traces of the pseudo-area parallel in both shells very near to borders of area. Peduncular groove broad, flat, parallel bordered. Thickening of shell slight, inner configuration slightly pronounced. Central depression of large shell pestle-shaped, at times indefinitely flattened. Septa and corneous processes receding very much. Median swelling of small shell strongly developed, divided by a sharp furrow between the places of attachment of the anterior lateral muscles. Places of attachment of the muscles distinctly pronounced. Those of the outside lateral muscles of large shell circular, standing off from those of the central muscles and mostly separated by a roundish swelling.

Observations: The few shells of this relatively rare species which are at hand in finest preservation do not allow some necessary characters of the visceral surface to be distinguished. Especially the impressions of the lateral vessels are withdrawn from observation, although just these characters, through their wonderful development and preservation in some species of the subgenus *Schmidtia* (e. g., in *O. celatus* and *O. crassus*), make possible in the highest degree the study of the vascular system in Eichwald's genus. Yet, in spite of the incomplete characterization, *O. obtusus* belongs to the best-defined species of the subgenus *Schmidtia*.

The peculiarity shows itself for the first in the predominant prolongation and the slight arching, which find their numerical expression in the respective value of $b:l$ and $h:l$. These relative numbers are in *O. obtusus* smaller than in all other species of the subgenus. * * *

To the longitudinally extended form now comes the broad obtuse-angled tip of the beak, which gives the shells a subrectangular outline, and by which *O. obtusus* is distinguished as well from all other species of the subgenus *Schmidtia* as from those of the other subgenera. The tip of the beak of a large shell loses its blunt form, and the rounded angle of the posterior border of the shell disappears, so that the outline becomes more broadly oval. In similar manner the small shell is changed. The corners of the blunted tip of the beak become round, and the rectilinearly truncate tip of the beak assumes a slightly convex form.

Of less specific account than the form, but not less striking to the eye, is the more considerable size of the shells, which surpasses that of all other species of the subgenus *Schmidtia*, the average length of the large shell being 6.47 mm., while the corresponding valve of the next largest species (*O. crassus*) only attains 5.96 mm. These results refer to the species with the exception of the varieties; of the latter, *O. obtusus longus* has a still more considerable length (7.7 mm.).

The exterior surface of the shell of a specimen figured shows some short, radially placed, slight furrows on the central part of the surface; the furrows are lacking on the posterior borders. This striation can, however, only be looked upon as an occasional formation, for, even if slight furrows of the same kind can be noticed in another specimen, they are entirely missing in all other shells examined. Isolated striæ of this kind also occur in the other *Schmidtia*s.

The formation of the area is very aberrant. While this part of the shell is generally triangular in the other species, it assumes in *O. obtusus* the form of a broad band, which hems the tip of the beak and is prolonged far into the borders of the shell. The splanchnocœlic part of the base of the area runs parallel to the borders of the beak and is, corresponding to the tip of the beak, angled in the peduncular furrow. In the small one it is rectilinear or slightly concave.

The surface of the area of the large shell sinks, as in *O. celatus*, only in a far stronger degree, from both sides toward the peduncular groove; besides this the whole surface of the area inclines obliquely toward the exterior, so that the borders of the beak recede from the surface of the border of the shell. The gap of the surface of the area in the peduncular groove is partly a consequence of the deficient thickening of the posterior part of the shell, which causes the lamellæ of the area to appear as a mere covering of the hollow tip of the beak; yet it is partly brought about by a slight lateral compression of the tip of the beak, which is also indicated at the exterior surface of the shell through a slight roundish median edge perceptible in reflected light. In the small shell these conditions occur in a similar manner, but stand out less distinctly.

Especially characteristic for this species is the position of the traces of the pseudo-area, which run parallel to the median line of the shell and are very near the lateral borders of the area. In some the posterior part of these traces seems to bend toward the tip of the beak with a roundish angle. Yet in nature the traces of the pseudo-area run rectilinearly to the posterior border of the beak and the deflecting apparent prolongations of the same are only accidental examples of more strongly sculptured striæ of the area.

This position of the traces of the area, which is far removed from the peduncular groove, appears to point to the relative size of the embryonal shells—a conjecture to which the consideration of the broad, parallel-bordered peduncular groove of *O. obtusus* has already led. In the small shell, the traces of the pseudo-area run exactly in the same manner, and inclose the flatly deepened splauncnœclic part of the area between them, which allows a shallow, rather broad groove in the median line, opposite the peduncular groove of the large shell, to be perceptible by reflected light.

The thickening of the shells is generally very slight, and therefore the configuration of the inner surface stands out but little. Nevertheless, predominant fluctuations occur also in this species. It is noteworthy that of all the formations which stand out from the surface of the shell, the median swelling of the small shell is the most given to variations, which often degenerate in a monstrous manner. * * * The heart-shaped groove is given to similar alterations of form as we have learned in *O. celatus*, and may be partly dependent on the strength of the thickening * * *.

The places of attachment of the muscles are in general distinctly pronounced, but not so sharply bordered as with the large forms of Eichwald's genus. Especially there are here also, as with *O. celatus*, the large central spots of attachment of the large shell, only with difficulty decomposable into their constituent parts. As with the previous species, the outside lateral muscles are delimited from the central muscles and form, close to the principal vascular canals, isolated, shallow-pitted, excavated places of attachment.

Of the principal vascular canals there can be distinguished on all the specimens at hand, in both shells, only the posterior parts; in the small shells, besides, as a rule, also the ends, curved around posteriorly and directed toward the places of attachment of the anterior lateral muscles. The first are very broad, flat, and divided by a median swelling, which often appears to be a prolongation of the lateral septa. The latter in no way deviates from the usual arrangement. Of the accessory vascular canals there can be observed only slight indications of the inwardly radiating canals, which show as somewhat lighter colored lines.

FORMATION AND LOCALITY.^a—Upper Cambrian: *Obolus* sandstone at the following localities: (395) At Joa, near Jegelecht, 12 miles (19.3 km.) east of Reval; and (395b) at Ilgast; both [Mickwitz, 1896, p. 171] in the Government of Esthonia, Russia.

(321c [Wiman, 1902, p. 68]) Drift boulder of *Obolus* sandstone, No. 17, on Fanton Island, parish of Börstil, Province of Stockholm, Sweden.

WESTONIA Walcott,^b subgenus of OBOLUS.

Obolus (*Westonia*) WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, pp. 683 and 691. (Described on latter page, as below, as a new subgenus.)

(*Westonia*) WALCOTT, MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, pp. 205–206. (Copies original description, and discusses the form as a subgenus more allied to *Lingulella* than *Obolus*.)

Lingulella GRABAU and SHIMER [NOT SALTER], 1907, North American Index Fossils, vol. 1, p. 192. (Described as *Lingulella*, but both species that are referred to it belong with *Obolus* (*Westonia*).)

Obolus (*Westonia*) WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 4, Pl. XI, and pp. 142 and 144. (Classification of genus.)

Ovate, with ventral valve slightly acuminate; area of ventral valve strongly defined and divided by a relatively large pedicle groove. Surface marked by concentric and radiating striæ that are crossed by transverse, semi-imbricating, "ripple-embossed" lines. So far as known, the muscle scars and vascular markings are essentially the same as in *Obolus*.

Type.—*Lingula aurora* Hall.

Of the species referred to *Westonia*, *Obolus* (*Westonia*) *aurora* (Hall), *O.* (*W.*) *ella* (Hall and Whitfield), *O.* (*W.*) *euglyphus* (Walcott), *O.* (*W.*) *chuaensis* (Walcott), *O.* (*W.*) *stoneanus*

^a Locality 395 is represented in the United States National Museum collections.

^b The synonymy for this subgenus does not give a complete record of the various genera under which the species now included in *Westonia* were formerly placed; it gives only those references in which the genus is discussed or described. To complete the record the following mere generic references are listed:

(Whitfield), *O. (W.) rogersi* (Walcott), *O. (W.?) lamellosus* (Barrande), and *O. (W.) escasoni* (Matthew) all have transverse, irregular, elevated lines. In *O. (W.) stoneanus* and *O. (W.) rogersi* these lines have two or three sharp undulations near the median line, and in *O. (W.) aurora* many short and more or less irregular undulations occur on the entire central portion of the shell. Beyond the short, central undulations, more or less wave-like, long undulations extend to the sides of the valve, usually with a slight backward curvature toward the margin.

Obolus (Westonia) finlandensis Walcott, *O. (W.) bottnicus* (Wiman), and *O. (W.) wimani* Walcott, of the Middle (possibly Lower) Cambrian sandstones of Sweden, differ in surface characters from the typical species of the genus. In these species the concentric lines and striæ of growth are well marked, also radiating lines that extend from the umbo irregularly toward the front and side margins of the shell. In addition there is a series of somewhat irregular striæ or lines that terminate at right angles to the lateral margin, start in toward the center of the shell, and then curve backward so as to meet at the center, or merge apparently into the radiating striæ (Pl. XLVIII, figs. 3 and 3a). These lines were apparently formed by the same agency (the front margin of the mantle) that formed the various irregular, more or less transverse lines on the other species of the genus. The two other species from the sandstones of Sweden, *O. (W.) ålandensis* Walcott and *O. (W.) balticus* Walcott, appear to have the typical *Westonia* surface represented on *O. (W.) ella*, although it is exceedingly fine.

The generic name was given in honor of Mr. T. C. Weston.

OBOLUS (WESTONIA) ÅLANDENSIS Walcott.

Plate XLVIII, figures 6, 6a.

Lingula? sp. No. 2, WIMAN, 1902, Bull. Geol. Inst. Univ. Upsala, vol. 6, pt. I, No. 11, p. 52, Pl. II, fig. 39. (Locality given.)

Lingulella? sp. No. 3, WIMAN, 1902, idem, p. 52, Pl. II, fig. 33. (Locality given. The specimen represented by fig. 33 is redrawn in this monograph, Pl. XLVIII, fig. 6.)

Lingulella? sp. No. 5, WIMAN, 1902, idem, p. 52, Pl. II, fig. 35. (Locality given. The specimen represented by fig. 35 is redrawn in this monograph, Pl. XLVIII, fig. 6a.)

Obolus (Westonia) ålandensis WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 334. (Discussed essentially as below as a new species.)

This species is characterized by its broad form when compared with *Obolus (Westonia) bottnicus* (Wiman), *O. (W.) wimani* Walcott, and *O. (W.) balticus* Walcott. Its surface is marked by fine concentric lines of growth, with very fine, threadlike, concentric striæ between them. In strong, reflected light, almost microscopic, transverse, very irregular lines can be seen that give the surface somewhat the appearance of that of *O. (W.) ella* (Hall and Whitfield).

For reference to the geological horizon of boulders on Eggegrund Island, similar to the ones containing this species, see description of *O. (W.) bottnicus* Walcott, p. 454.

The species derives its specific name from its occurrence on Åland Island.

FORMATION AND LOCALITY.—Middle? Cambrian: (311j and 311k) Drift boulders of bituminous sandstone, Nos. 28 and 29 [Wiman, 1902, p. 57], on Biludden, about 20 miles (32.2 km.) east of Gefle, Province of Gefleborg; and (311m) drift boulder of bituminous sandstone, No. 1 [Wiman, 1902, p. 57], on Limön Island, about 12 miles (19.3 km.) northeast of Gefle, Province of Gefleborg; all in Sweden.

(311y) Drift boulder of rusty sandstone [Wiman, 1902, p. 57], at Ytternäs, Slemmern, Åland Island, Finland, Russia.

Lingula aurora Hall, SARDESON, 1896, Bull. Minnesota Acad. Nat. Sci., vol. 4, No. 1, pt. 1, p. 95. (New localities mentioned.)

Obolus (*Westonia*) *aurora* (Hall), WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 691. (Merely changes generic reference.)

Lingulella aurora (Hall), GRABAU and SHIMER, 1907, North American Index Fossils, vol. 1, p. 193. (Described.)

General form broadly ovate, with the dorsal valve almost subcircular, except for the gentle slope of the cardinal margins toward the low obtuse beak. The beak of the ventral valve is almost invariably broken off, as shown in Plate XLVI, figures 1a to 1d. If the cardinal slopes are restored, as in figure 1c, the form of the beak is rather obtuse. Original convexity unknown, as all of the large number of specimens in the collection are compressed and often flattened on the surface of the shaly sandstone. It appears to have been moderate like that of *Lingulella ampla* (Owen) and *Obolus* (*Westonia*) *stoneanus* (Whitfield). The shell appears to have been built up of a thin outer layer and thin lamellose inner layers. On some of the casts of the valves the character of both the inner and outer surface markings is shown.

The outer surface of the shell is marked by concentric striæ and lines of growth and a complex system of lamellose striæ. The latter are almost directly transverse near the sides of the shell and curve slightly backward over the central portion, where they have a sharp zigzag character that is highly characteristic (Pl. XLVI, figs. 1g and 1h). When the outer surface of the shell is exfoliated the surface is marked by concentric lines and striæ and fine radiating striæ (figs. 1 and 1b). This latter surface is probably caused by the markings of the inner surface of the shell and the inner surface of the outer layer or lamella, as is seen so frequently in the shell of *Lingulella acutangula* (Roemer) (Pl. XVII) and *Dicellomus politus* (Hall) (Pl. LII). The appearance of several specimens leads to the conclusion that the interior surface was more or less punctate. It frequently happens that the outer surface of the shell is worn nearly smooth, the only remaining traces of the beautiful surface ornamentation being toward the beak, or a spot here and there protected by a strong raised line of growth.

This is one of the largest shells of the genus. A ventral valve from Mazomanie is 21 mm. long, with a maximum width of 17 mm., and an associated dorsal valve is 17.5 mm. long and 17 mm. in width. The cardinal area is well defined in both valves. In the ventral valve it is divided at the center by a strong pedicle groove and toward its margins by narrow, clearly defined flexure lines. The striæ of growth cross the area parallel with its base (Pl. XLVI, fig. 1c).

The area formed a thin shelf between the pedicle groove and the lateral margins, and the undercut extended back beneath the area, but how far can not be determined, as the cast of it is broken away in the specimens in the collection.

The area of the dorsal valve is short as compared with that of the ventral valve. It extends well out on the cardinal slopes, and has a very faintly indicated flexure line near the lateral margin. The cast of the visceral cavity (v) is partly shown in figure 1a. There is a peculiar apron-like area that extends forward from the flattened cast of the pedicle groove (Pl. XLVI, figs. 1b-d) that probably represents a broad groove that existed in the interior of the shell back of the visceral cavity. No clearly defined muscle scars have been observed.

Observations.—The surface ornamentation is very characteristic, and is of the same general type as that of *Obolus* (*Westonia*) *ella*. (Compare Pl. XLVI, fig. 1h, with Pl. XLVII, fig. 1o.)

The outline of the valves is somewhat like that of *Lingulella ampla* (Owen) (Pl. XXVIII). It differs in being wider in proportion to the length. As pointed out by Hall, *Obolus* (*Westonia*) *aurora* is from the upper beds at Mazomanie and *Lingulella ampla* from the lower beds at Trempealeau.

FORMATION AND LOCALITY.—Upper Cambrian: (S85x)^a In the upper beds of the "St. Croix sandstone," near Mazomanie, Dane County; (85s) "St. Croix sandstone," at Prairie du Sac, Sauk County; (78, 78c, and 78s) "St. Croix sandstone" at Osceola, Polk County; (79) "St. Croix sandstone," in bluff near Hudson, St. Croix County; (86) "St.

^a S85x is the type locality, though the specimens in the United States National Museum collections to which that number is assigned were collected much later than the type specimens. The species also occurs in Localities 3281 and 328p.

Croix sandstone," at Van Ness quarry, Gibraltar Bluff, Lodi, Columbia County; and (328b) St. Lawrence formation [Sardeson, 1896, p. 95], at Osceola, Polk County; all in Wisconsin.

(339a) St. Lawrence formation [Sardeson, 1896, p. 95], at Otisville, Washington County; and (97 and 339c) Reeds Landing, foot of Lake Pepin, Wabasha County; both in Minnesota.

OBOLUS (WESTONIA) BALTICUS Walcott.

Plate XLVIII, figures 7, 7a-b.

Lingulella? sp. No. 4, WIMAN, 1902, Bull. Geol. Inst. Univ. Upsala, vol. 6, pt. 1, No. 11, p. 52, Pl. II, figs. 37 and 38. (Locality given. The specimens represented by figs. 37 and 38 are redrawn in this monograph, Pl. XLVIII, figs. 7a and 7b, respectively.)

Lingulella? sp. No. 6, WIMAN, 1902, idem, p. 52, Pl. II, fig. 34. (Locality given. The specimen represented by fig. 34 is redrawn in this monograph, Pl. XLVIII, fig. 7.)

Obolus (Westonia) baltica WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 334. (Characterized as below as a new species.)

This species is characterized by its elongate form, with the sides of the dorsal valves regularly rounded from the back to the rounded frontal margin. The dorsal valves are also more regularly and strongly convex than in other species occurring in the Cambrian sandstones of Sweden. The outer surface is marked by concentric and radiating striæ, crossed obliquely by very fine, irregular transverse striæ. The latter are only to be seen with a strong magnifier and favorable light.

For reference to the geologic horizon of boulders on Eggegrund Island, similar to the ones containing this species, see description of *Obolus (Westonia) bottnicus*, page 454.

The species derives its name from its occurrence in the North Baltic region.

FORMATION AND LOCALITY.—Middle? Cambrian: (311h) Drift boulder of bituminous sandstone, No. 26 [Wiman, 1902, p. 57], on Biludden, about 20 miles (32.2 km.) east of Gefle; and (311o) drift boulder of bituminous sandstone, No. 1 [Wiman, 1902, p. 57], on Skälstenarne Island, just west of Eggegrund Island, about 25 miles (40 km.) east-northeast of Gefle; both in the Province of Gefleborg, Sweden.

(311t) Drift boulder of mottled calcareous sandstone [Wiman, 1902, p. 57], at Öiverby, parish of Jomala, Åland Island, Finland, Russia.

OBOLUS (WESTONIA) BLACKWELDERI Walcott.

Plate XXXIX, figures 10, 10a-c.

Obolus (Westonia) blackwelderi WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, p. 335. (Described and discussed as below as a new species.)

General form elongate, with the width about one-half the length; front margin broadly rounded; sides slightly arched up to the lateral slopes, which are quite straight in the ventral valve and curved toward the rounded posterior end of the dorsal valve; the beak of the ventral valve is pointed and marginal. The convexity of the valves is moderate, that of the dorsal apparently being the greater. Surface marked by concentric striæ and lines of growth which are crossed by irregular, fine, imbricating, more or less transverse lines; the transverse lines trend slightly backward toward the sides of the valves. A dorsal valve 8 mm. in length has a width of 5 mm.

Observations.—Nothing is known of the interior of the valves. When the shell is broken from the limestone, the outer surface usually adheres to the matrix. The best exteriors are those of shells on the surface of the layers. Of the known species of *Westonia*, *O. (W.) wimani* Walcott, and *O. (W.) balticus* Walcott are most nearly related to *O. (W.) blackwelderi*. The latter is a larger shell and also less narrow proportionally where the gently arching sides pass into the posterolateral slopes.

The specific name is given for Prof. Eliot Blackwelder, of the University of Wisconsin, who collected the specimens.

FORMATION AND LOCALITY.—Middle Cambrian: (C1 and C2) Lower shale member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 40 (part of the 3d list of fossils), and fig. 10 (bed 4), p. 38], 2 miles (3.2 km.) south of Yenchuang; and (C6) thin slabby limestone in the upper shale member of the Kiulung group [Blackwelder, 1907a, pp. 37 and 41 (2d list of fossils), and fig. 10 (bed 12), p. 38], 2.5 miles (4 km.) southwest of Yenchuang; both in the Sintai district, Shantung, China.

OBOLUS (WESTONIA) BOTTNICUS (Wiman).

Plate XLVIII, figures 4, 4a-c.

Lingula bottnica WIMAN, 1902, Bull. Geol. Inst. Univ. Upsala, vol. 6, pt. 1, No. 11, p. 51, Pl. II, figs. 40-44. (Characterized and discussed in German as a new species. The specimens represented by figs. 41, 42, 43, and 44 are redrawn in this monograph, Pl. XLVIII, figs. 4, 4a, 4b, and 4c, respectively.)

Obolus (Westonia) bottnica (Wiman), WALCOTT, 1905, Proc. U. S. Nat. Mus., vol. 28, pp. 335-336. (Characterized and discussed as below.)

The description of *Obolus (Westonia) finlandensis* Walcott so closely applies to this species that it is only necessary to point out the difference between the two and to compare the figures illustrating them.

The surface of *Obolus (Westonia) bottnicus* has the same concentric and radiating lines with the irregular, transverse lines terminating at right angles to the margins, curving inward and backward in such a manner as obliquely to cross the radiating lines that extend from the umbo forward to the anterior and anterolateral margins. The central scars of the dorsal valve are much farther forward in *O. (W.) bottnicus*.

Wiman [1902, p. 51] refers this species to the *Olenellus* sandstone series. The boulder containing it also carried *Aparchites? anderssoni*, *Hipponicharion matthewi*, *Acrotreta eggegrundensis*, *Kutorgina?*, *Torellella lævigata*, and fragments referred to *Olenellus*. This fauna is essentially Middle Cambrian in its facies and unless the fragments referred to *Olenellus* are indisputably of that genus, I am inclined to refer the boulder and its contained fossils to the Middle Cambrian. The fact that *Obolus (Westonia) bottnicus* is nearly identical with *O. (W.) finlandensis* of the Middle Cambrian of Finland also points to the Middle Cambrian age of the fauna.

The specific name is derived from the Swedish form of the word Bothnia.

FORMATION AND LOCALITY.—Middle? Cambrian: (311) Drift boulder of coarse-grained, somewhat friable, glauconitic sandstone, No. 3 [Wiman, 1902, p. 57], on Eggegrund Island, about 25 miles (40 km.) east-northeast of Gefle, Province of Gefleborg, Sweden.

Specimens which were doubtfully referred to this species by Wiman occur at the following locality:

Middle? Cambrian: (311e) Drift boulder of rusty sandstone [Wiman, 1902, p. 57], south of Lumparn, parish of Jomala, Åland Island, Finland, Russia.

OBOLUS (WESTONIA) CHUARENSIS (Walcott).

Plate XXV, figures 2, 2a-e.

Obolus (Lingulella) chuarensis WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, p. 399. (Described and discussed essentially as below as a new species.)

Obolus (Westonia) chuarensis WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 691. (Merely changes generic reference.)

General form broadly ovate, almost subquadrate, with the ventral valve obtusely acuminate, and the dorsal valve rounded subquadrate, the posterior margin being broadly obtuse; convexity moderate, increasing somewhat in the older shells. Surface of shell marked by rather strong, concentric lines and striæ of growth and very fine, more or less transverse and irregular, apparently imbricating striæ such as ornament the surface of *Obolus (Westonia) ella* (Hall and Whitfield) and *O. (W.) euglyphus* (Walcott). Fine radiating striæ also appear under a strong magnifying glass. When the outer surface is exfoliated the inner layers of the shell show traces of radiating striæ. The inner surface is marked by pits or punctæ, arranged in more or less irregular concentric lines; also fine radiating striæ. The shell is strong and formed of a thin outer layer and several inner layers or lamellæ, those near the outer margin being arranged obliquely to the outer surface.

The only traces of the interior markings are those on the casts of the dorsal valve. These show a short and rather broad area, strong vascular sinuses, and traces of the anterior lateral muscle scars.

Observations.—The character of the surface ornamentation and subquadrate form of the dorsal valve lead to a comparison with *O. (W.) ella* (Hall and Whitfield) (Pl. XLVII) of the Rocky Mountain fauna. The species differs from the latter in having a thicker, stronger shell, relatively shorter in proportion to its length. The surface is also of the same type as that of *O. (W.) euglyphus* (Walcott) (Pl. XLVIII), which occurs at the same horizon in the upper portion of the "Tonto" sandstone but not associated with it. It differs from *O. (W.) euglyphus* in being much shorter and broader in proportion to its length.

The species derives its name from its occurrence in the Chuar Valley, Grand Canyon of the Colorado, Arizona.

FORMATION AND LOCALITY.—**Middle Cambrian:** (74) Sandstone about 300 feet (91.4 m.) above the base of the Tonto group at the head of Nunkoveap Valley; (74b) sandstone about 1,000 feet (305 m.) above the base of the Tonto group, at the head of Nunkoveap Valley; (73) sandstones of the Tonto group in Kwagunt Valley; and (73a) "Tonto" sandstone, in Chuar Valley; all in the Grand Canyon of the Colorado, Arizona.

OBOLUS (WESTONIA) DARTONI (Walcott).

Text figures 40A–C.

Obolus (Westonia) dartoni WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 67, Pl. VII, fig. 14. (Discussed as below as a new species. Fig. 14 is reproduced below, fig. 40A.)

This species has the general form and convexity of *Obolus (Westonia) euglyphus* (Walcott) (Pl. XLVIII, figs. 1, 1a–e). It differs in the dorsal valve being narrower posteriorly. The surface of the two species differs very much, that of *O. (W.) dartoni* being of the *O. (W.) ella* (Hall and Whitfield) type (Pl. XLVII, fig. 1o) and not like that of *O. (W.) euglyphus* (Pl. XLVIII, fig. 1f). From *O. (W.) ella* this species differs in being more elongate in outline and in having the surface more clearly marked by the crossing of the minute ridges. These ridges are slightly irregular and curve from near the umbo obliquely across the shell toward the lateral and front margins so as to form a pattern much like that shown on the front portion of Plate XLVII, figure 1e. Some portions of the surface recall that of the central portions of Plate XLVI, figure 1h. The largest ventral valve has an indicated length of 12 to 15 mm.; width, 9 mm.

The specific name was given for Mr. N. H. Darton, of the United States Geological Survey, who collected the specimens.

FORMATION AND LOCALITY.—**Middle Cambrian:** (302o) Sandstones just above the granite, west of Garfield Peak, 50 miles (80.5 km.) west of Casper, Natrona County, Wyoming.

OBOLUS (WESTONIA) ELLA (Hall and Whitfield.)

Plate XXXIII, figures 3, 3a–c; Plate XLVII, figures 1, 1a–p.

Lingulepis ella HALL and WHITFIELD, 1877, U. S. Geol. Expl. 40th Par., vol. 4, p. 232, Pl. I, fig. 8. (Described and discussed as a new species. The specimen represented by fig. 8 is redrawn in this monograph, Pl. XLVII, fig. 1b.)

Lingulella ella (Hall and Whitfield), WALCOTT (in part), 1886, Bull. U. S. Geol. Survey No. 30, pp. 97–98, Pl. VII, fig. 2; Pl. VIII, figs. 4, 4a, 4d, and 4e (not figs. 4b and 4c, now referred to *Lingulella dubia*). (Copies original description and describes and discusses species. Fig. 4 is redrawn from the specimen represented in fig. 8 of the preceding reference. The specimens represented by figs. 2 and 4 are redrawn in this monograph, Pl. XLVII, figs. 1m and 1b, respectively.)

- Lingulella ella* (Hall and Whitfield), ПАЕК, 1906, Jour. Geol., vol. 14, No. 4, p. 295, Pl. I, figs. 2 and 2a. (Mentioned, and new localities given.)
- Lingulella* (*Westonia*) *ella* (Hall and Whitfield), GRABAU and SHIMER, 1907, North American Index Fossils, vol. 1, p. 193, figs. 229a-b. (Described. Figs. 229a-b are copied from Walcott [1886b, Pl. VIII, figs. 4 and 4a, respectively].)

General form broad ovate, with the dorsal valve subquadrate or rounded quadrate and the ventral valve obtusely acuminate; valves moderately convex, so far as can be determined from the crushed and flattened specimens from the shales of Utah and Nevada. Surface of the shell marked by concentric striæ and lines of growth and, on the type specimen, by very fine, irregular, lamellose, more or less transverse striæ and fine radiating lines; the surface is much like that of *O. (W.) euglyphus* (Walcott) (Pl. XLVIII); fine, clearly defined radiating lines occur on the inner layer of the shell of partly exfoliated specimens. The cast of the inner surface of the shell shows papillæ that filled punctæ in the shell; they are rather large and are arranged in the central portion of the shell in concentric lines, much as in *Lingulella davisi*. The shell is strong and rather thick in old shells. It is made up of a thin outer layer and several inner layers or lamellæ that are well shown in the figure of the type specimen (Pl. XLVII, fig. 1b).

The largest ventral valve thus far examined has a length of 16 mm. and a width of 13 mm. A dorsal valve is 13 mm. long by 12.5 mm. in width.

The area of the ventral valve is of the same type as that of *O. (W.) aurora* (Hall) (Pl. XLVI) and *Lingulella ampla* (Owen) (Pl. XXVIII). The flexure line is nearer the pedicle furrow than in *Lingulella perattenuata* (Whitfield) (Pl. XXI), *L. acutangula* (Roemer) (Pl. XVII), *Lingulella ampla*, and *Obolus (Westonia) aurora*, which results in a wider outer lateral space on the area (Pl. XLVII, fig. 1c (a')). The pedicle furrow is strong and deeply rounded, and in one specimen referred to this species (Pl. XLVII, figs. 1d and 1g) the cast of the base of the undercut between the area and the outer shell is clearly shown on each side of the pedicle groove. The area of the dorsal valve is low and broad; the flexure lines cross it so as to form a broad, slightly elevated space in the cast corresponding to a broad, shallow furrow in the shell (Pl. XLVII, fig. 1i). The striæ of growth cross the area parallel with its base, both in the ventral and dorsal valves.

The cast of the interior of the ventral valve shows the visceral cavity (Pl. XLVII, figs. 1c, 1d, and 1g) and the median septum of the dorsal valve is seen in figures 1i and 1k.

The muscle scars are not distinctly shown on the ventral valve. In the dorsal valve the central scars (h) are preserved in specimens from Nevada (fig. 1i) and Montana (figs. 1 and 1k), and the anterior laterals in Plate XLVII, figures 1k and 1l.

The remains of markings made by the vascular system are limited to the main or trunk sinuses of the two valves, and a portion of the parietal scar (ps) is seen on one specimen of the ventral valve (Pl. XLVII, fig. 1g).

Observations.—The type specimen of this species is a somewhat crushed dorsal valve that fortunately preserves the outer surface and much of the shell. Near the type locality, and in the same band of slaty shales, were found a number of specimens, including a series of young shells. Two of the larger shells are shown by Plate XLVII, figures 1 and 1a, and two of the

young by figures 1e and 1f. The shells found near Helena, Montana, commonly occur as casts in a siliceous shale and have the form of and appear to be specifically identical with the species in the Wasatch and Oquirrh mountains. A few specimens preserve the shell and show it to be thick and strongly laminated toward the front.

The form from the Bighorn Mountains of Wyoming appears to be identical with this species, except that the surface ornamentation is coarser and much more distinctly outlined by the zigzag, irregular, transverse striae. The strength of the striae and the size of the more or less rhombic interspaces range from near those of *O. (W.) ella* to more than double their size, the increase in the size of the interspaces being made more prominent by the deposition of what appears to be chalcedony on the outer surface or a replacement of the shell by chalcedony. The form of the valves and the position of the central and anterior lateral muscle scars in the dorsal valve are essentially the same as in *O. (W.) ella*.

On Gordon Creek in Montana this species occurs in association with the *Albertella helena* fauna [Walcott, 1908f, p. 202], which is referred to the highest zone of the Lower Cambrian. Four small ventral valves were found that have the form and surface characteristic of *Obolus (Westonia) ella*.

Obolus (Westonia) ella has a wide geographic distribution in the Cordilleran and southern Appalachian regions. It also has a vertical range from the summit of the Lower Cambrian in Montana and British Columbia to 250 feet up in the Upper Cambrian.

FORMATION AND LOCALITY.—**Upper Cambrian:** (4y and 54t) Limestone of the St. Charles formation [Walcott, 1908a, p. 6], about 250 feet (76 m.) above the Middle Cambrian on the north side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County, Idaho.

(54e) About 200 feet (61 m.) above the Middle Cambrian and 1,025 feet (212.4 m.) below the top of the Upper Cambrian in limestones forming 3 of the St. Charles formation [Walcott, 1908f, p. 193], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County, Utah.

Middle Cambrian: (57g) About 1,700 feet (518 m.) above the Lower Cambrian and 3,250 feet (991 m.) below the Upper Cambrian, in the siliceous shales forming 2d of the Stephen formation [Walcott, 1908f, p. 211], on Mount Bosworth, north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide, between British Columbia and Alberta, Canada.

(5f) Limestone interbedded in the Wolsey shale [Weed, 1900, p. 285], in Meagher County, on the road to Wolsey, about 4 miles (6.4 km.) south of the divide at the head of Sawmill Creek, and 11 miles (17.7 km.) south of Neihart, Little Belt Mountains quadrangle (U. S. Geol. Survey), Cascade County; (340a) shales near Helena, Lewis and Clark County; (302s) dark siliceous shale in a quarry in Last Chance Gulch, south slope of Mount Helena, 1.5 miles (2.4 km.) south of Helena, Lewis and Clark County; (4u) shales in the Gallatin formation of Peale [1893, Pl. IV], northwest side of canyon 0.5 mile (0.8 km.) south of Helena, Lewis and Clark County; (9m) shale 4 miles (6.4 km.) above Walker's ranch, on North Fork of Dearborn River, in the eastern part of the Lewis and Clark National Forest, Lewis and Clark County; (4q') limestone about 310 feet (94.5 m.) above the unconformable base of the Cambrian and 185 feet (56.4 m.) above the top of the quartzitic sandstones in a shale which corresponds in stratigraphic position to the upper part of shale No. 6 of the Dearborn River section [Walcott, 1908f, p. 202], on the ridge between Gordon and Youngs creeks, about halfway between Gordon Mountain and Cardinal Peak, Ovando quadrangle (U. S. Geol. Survey), Powell County; (4k) about 725 feet (221 m.) above the base of the Cambrian in the shales of the Gallatin formation of Peale [1893, Pl. IV], on the north side of West Gallatin (Gallatin) River, northeast of Logan, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County; and (4g) about 325 feet (99.1 m.) above the base of the Cambrian in the Flathead shales of Peale [1893, p. 21], 1 mile (1.6 km.) north of the junction of East Gallatin and West Gallatin (Gallatin) rivers, 4 miles (6.4 km.) east-northeast of Logan, Threeforks quadrangle (U. S. Geol. Survey), Gallatin County; all in Montana.

(5h and 55d) About 2,000 feet (609.6 m.) above the Cambrian quartzitic beds in a shale which is probably to be referred to the Bloomington formation [Walcott, 1908a, p. 7], on the south side of Twomile Canyon, near its mouth, 2 miles (3.2 km.) southeast of Malade, Oneida County; and (55c) Spence shale member of the Ute limestone [Walcott, 1908a, p. 8], about 50 feet (15.2 m.) above the Brigham quartzite and 2,755 feet (839.7 m.) below the Upper Cambrian, in a ravine running up into Danish Flat from Mill Canyon, about 6 miles (9.6 km.) west-southwest of Liberty and 15 miles (24.2 km.) west of Montpelier, Bear Lake County; both in Idaho.

(171a) Sandstone in Big Goose Creek Canyon, in the Bighorn Mountains, west of Sheridan, Sheridan County; and (4n) limestone about 325 feet (99.1 m.) above the unconformable base of the Cambrian in divide at the head of Jackson Creek (locally known as Sheep Creek), a creek flowing into Jackson Lake about 0.5 mile (0.8 km.) south of its northwestern corner, Teton Mountains, Grand Teton quadrangle (U. S. Geol. Survey), Uinta County; both in Wyoming.

(3g) Shales on the river bank 250 feet (76.2 m.) above the west end of the Denver and Rio Grande Railroad tunnel, Glenwood Springs, Garfield County, Colorado.

(329c) In Weber Canyon, about 2.5 miles (4 km.) northeast of Peterson, Morgan County; (30p) about 125 feet (38 m.) above the Cambrian quartzitic sandstones, on the north side of Ogden Canyon, about 1 mile (1.6 km.) above its mouth, east of Ogden, Weber County; and (30a) shale on north side of Big Cottonwood Canyon, 1 mile (1.6 km.) below Argenta, Wasatch Range, southeast of Salt Lake City, Salt Lake County; all in Utah.

(32y) Shales about 175 feet (53.3 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in the Wasatch Mountains, 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham; (32p and 55e) Spence shale member of the Ute limestone, about 100 feet (30.5 m.) above the Brigham quartzite [Walcott, 1908f, p. 197], in Wasatch Canyon, east of Lakeview Ranch, 5 miles (8 km.) north of Brigham; and (329) *green shales in a canyon about 7 miles (11.2 km.) north of Brigham (near the village of "Calls Fort" [Haguc, 1877, p. 405])*; all in Boxelder County, Utah.

(31e and 54a) About 750 feet (228.6 m.) above the Brigham quartzite and 3,440 feet (1,048.5 m.) below the Upper Cambrian, in the shales forming 2a of the Ute limestone [Walcott, 1908f, p. 196], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum; (32d) shales about 150 feet (45.7 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], on the east side of the south fork of Paradise Dry Canyon (locally known as East Fork), east of Paradise; and (31z and 55t) about 350 feet (106.7 m.) above the Brigham quartzite, in the Ute limestone [Walcott, 1908a, p. 7], on west side of road 0.5 mile (0.8 km.) above the forks, Paradise Dry Canyon, east of Paradise; all east of Cache Valley, Cache County, Utah.

(32o) Shale about 325 feet (99 m.) above the Cambrian quartzitic sandstones, 2 miles (3.2 km.) southeast of Muskrat Spring, on the northwest face of Grantsville Peak, Stansbury Range; (3d) concretionary limestone about 100 feet (30.5 m.) above the Cambrian quartzitic sandstones, at Ophir, Oquirrh Range; (329e) shales in East Canyon, above Ophir, Oquirrh Range; (3c) shales about 75 feet (22.9 m.) above the Cambrian quartzitic sandstones, at Ophir, Oquirrh Range; and (32h and 32z) shales in a canyon on the west side of the Simpson Range, 4 miles (6.4 km.) south of Simpson Spring, about 20 miles (32.2 km.) west-southwest of Vernon; all in Tooele County, Utah.

(30d) About 1,020 feet (310.9 m.) above the Lower Cambrian and 3,400 feet (1,036.3 m.) below the Upper Cambrian in the limestone forming 1e of the Swasey formation [Walcott, 1908f, p. 182], at the head of Dome Canyon; and (31s) 490 feet (149.4 m.) above the Lower Cambrian and 3,925 feet (1,196.3 m.) below the Upper Cambrian in the pinkish argillaceous shale forming 1d of the Howell formation [Walcott, 1908f, p. 182], south side of Dome Canyon about 1 mile (1.6 km.) below the divide; both about 3 miles (4.8 km.) west-southwest of Antelope Springs, House Range [Walcott, 1908f, Pl. XIII], Millard County, Utah.

(31) Shales on the dump of the Chisholm mine; (333b [Pack, 1906, p. 295]) shales on the dump of the Half-moon mine; (333a [Pack, 1906, p. 295]) shales on the dump of the Himon mine; (333 [Pack, 1906, p. 295]) shales on the dump of the Abe Lincoln mine; (7k) shales in the dumps of the Half-moon and Chisholm mines, southwest slope of Ely Mountains; and (31u) shales on the west slope of the spur facing the main part of the Highland Range; all about 3 miles (4.8 km.) northwest of Pioche, Lincoln County, Nevada.

(90) Conasauga ("Coosa") shale, on Edwards farm, near Craigs Mountain, about 10 miles (16.1 km.) southeast of Center, Cherokee County; and (141a) limestone 0.25 mile (0.4 km.) west of the hotel at Montevallo, Shelby County; both in Alabama.

(14a) Sandstone of the Rome formation along First Creek Gap, 4 miles (6.4 km.) north-northeast of Knoxville [Keith, 1905, areal geology sheet], Knox County, Tennessee.

Lower Cambrian: (4v) About 200 feet (61 m.) above the unconformable base of the Cambrian and 75 feet (22.9 m.) above the top of the quartzitic sandstones in a shale which corresponds in stratigraphic position to shale No. 6 of the Dearborn River section [Walcott, 1908f, p. 202], on Gordon Creek, 6 miles (9.6 km.) from South Fork of Flathead River, Ovando quadrangle (U. S. Geol. Survey), Powell County, Montana.

(33i) About 100 feet (30.5 m.) above the Prospect Mountain quartzite in the shales of the Pioche formation [Walcott, 1908f, p. 171], 0.25 mile (0.4 km.) below the Maxfield mine, Big Cottonwood Canyon, west front of the Wasatch Mountains, southeast of Salt Lake City, Salt Lake County, Utah.

(30) Eight miles (12.8 km.) north of Bennetts Spring, on the west slope of the Highland Range, Lincoln County, Nevada.

Specimens that are somewhat doubtfully referred to *Obolus (Westonia) ella* occur at the following localities:

Middle Cambrian: (57y) About 1,900 feet (579 m.) above the Lower Cambrian and 3,050 feet (930 m.) below the Upper Cambrian, in the siliceous shales forming 2a of the Stephen formation [Walcott, 1908f, p. 211], on Mount Bosworth, north of the Canadian Pacific Railway between Hector and Stephen, on the Continental Divide between British Columbia and Alberta, Canada.

(31d and 54l) About 500 feet (152.4 m.) above the Brigham quartzite and 3,700 feet (1,127.8 m.) below the Upper Cambrian, in the Spence shale member of the Ute limestone [Walcott, 1908f, p. 197], in Blacksmith Fork Canyon, about 10 miles (16.1 km.) east of Hyrum, Cache County; (32n) shales about 725 feet (221 m.) above the Brigham quartzite [Walcott, 1908a, p. 8], in the Wasatch Mountains, 1 mile (1.6 km.) northwest of Geneva (Copenhagen), east of Brigham, Boxelder County; and (11s) shales just above Simpson Spring, about 20 miles (32.2 km.) west-southwest of Vernon, on the stage road from Vernon to Fish Springs, Tooele County; all in Utah.

OBOLUS (WESTONIA) ELLA ONAQUIENSIS Walcott.

Plate XLIX, figures 6, 6a.

Obolus (Westonia) ella onaquiensis WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, pp. 67-68. (Discussed as below as a new variety.)

This variety is represented by a number of more or less imperfect specimens that at first sight might be placed with *Obolus (Westonia) ella* (Hall and Whitfield), but the character of the surface clearly distinguishes the two forms. In typical forms of *O. (W.) ella* the transverse striæ are more regular, while in this variety they are in the form of sharp, finely zigzag, transverse striæ much like the shells of the species from the Bighorn Mountains. This surface is formed by the interruption of very fine sharp ridges that curve from the umbo outward toward the sides and front of the shell like engine-turned striæ on a watch case.

This form derives its varietal name from its occurrence in the Onaqui Range of Utah.

FORMATION AND LOCALITY.—**Middle Cambrian:** (33f) Shales about 400 feet (122 m.) above the Cambrian quartzitic sandstones, on the western slope of the high peak southwest of Lookout Pass, Onaqui Range, west of Vernon, Tooele County, Utah.

OBOLUS (WESTONIA) ELONGATUS Walcott.

Plate LXIII, figures 8, 8a-d.

Obolus (Westonia) elongatus WALCOTT, 1908, Smithsonian Misc. Coll., vol. 53, No. 3, p. 68, Pl. VII, fig. 12. (Described and discussed as below as a new species. Fig. 12 is copied in this monograph, Pl. LXIII, fig. 8a.)

General form elongate oval, with the ventral valve acuminate and the dorsal valve elongate oval. Convexity unknown, as the shells are all flattened by compression.

The outer surface is marked by fine concentric lines of growth crossed by a series of finely denticulated, imbricating lines that start on each cardinal slope and extend obliquely forward across the median line, and then curve out toward the sides of the shell; minute rhomboidal spaces are formed over the posterior and central portions of the shell by the crossing of the oblique lines; the denticulated margin faces forward and is seen only on the thin epidermal layer, while the general system of oblique lines shows on both the outer layer and the next inner layer of the shell.

The shell is built up of several thin layers or lamellæ. The largest specimen of the ventral valve has a length of 9 mm.; width, 5 mm.; a dorsal valve 6 mm. long has a width of 4 mm. Nothing is known of the interior of these valves.

Observations.—This is a more elongate species than *Obolus (Westonia) bottnicus* Walcott and *O. (W.) finlandensis* Walcott. The oblique surface lines have the same general direction as those of the latter species, but they are finely denticulated on their front margin, and cross at the center at a greater angle.

FORMATION AND LOCALITY.—**Middle Ordovician:** (105x) Gray, siliceous shales, just below a band of quartzitic sandstones, probably corresponding in position to the upper part of the Simpson formation of the Oklahoma section, Wasatch Canyon, east of Lakeview Ranch, about 5 miles (8 km.) north of Brigham, Boxelder County, Utah.

OBOLUS (WESTONIA) ESCASONI (Matthew).

Plate XLIX, figures 1, 1a-f.

Lingulella (?) escasoni MATTHEW, 1901, Bull. Nat. Hist. Soc. New Brunswick, vol. 4, pt. 4, No. 19, pp. 270-273, Pl. V, figs. 1a-i. (Described and discussed as a new species. The specimens represented by figs. 1d and 1g are redrawn in this monograph, Pl. XLIX, figs. 1b and 1a, 1aa, respectively.)

Obolus (Westonia) escasoni (Matthew), WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 691. (Merely changes generic reference.)

Westonia escasoni MATTHEW, 1903, Geol. Survey Canada, Rept. Cambrian Rocks Cape Breton, pp. 206-209, Pl. XVI, figs. 1a-i. (Copied from Matthew, 1901a, pp. 270-273, Pl. V, figs. 1a-i.)

General form ovate, with the ventral valve broadly subacuminate and the dorsal valve rounded oval in outline. The valves are moderately convex, the ventral being most prominent

toward the beak. The convexity gives a depth of about 1 mm. to shells 5 mm. in diameter. Surface marked by radiating striæ, concentric lines of growth, and fine, more or less undulating transverse striæ. When the thin outer layer of the shell is exfoliated, the next layer is marked by rather strong, radiating striæ and concentric striæ and lines of growth. The inner surface of the shell is strongly pitted, even over the visceral area, and the anterior and lateral margins are marked by the impressions of the fine canals of the vascular system. The character of the transverse lines is fully shown by Plate XLIX, figure 1f.

The shell is relatively thick, and formed of a very thin outer layer and several inner layers or lamellæ, which are more or less oblique to the outer layer. These layers are well shown by the posterior portion of Plate XLIX, figure 1a.

The shell is small, the largest not exceeding 6 mm. in length. The dorsal valve is slightly shorter than the ventral. The relative dimensions of the two valves may be seen by comparing figures 1 and 1b of Plate XLIX.

The details of the area of the ventral valve are not well shown by any specimens in the collection. The pedicle groove appears to have been well marked, and the area to have extended a short distance out on the cardinal slopes. The area of the dorsal valve is larger in proportion than usual when compared with that of the ventral valve. The striæ of growth cross it parallel to the anterior margin.

The interior of the ventral valve is shown by Plate XLIX, figure 1a, which beautifully preserves the central portion, and by the cast (fig. 1). The heart-shaped pit (x), so characteristic of *Obolus*, is clearly defined in figure 1a, where it strongly resembles the same space in *Obolus apollinis* Eichwald (Pl. VII). No traces of a median septum have been observed in the ventral valve, but in the dorsal valve the median ridge extends from back of the central muscle scars to the anterior lateral scars. A strong, pestle-shaped depression extends in the ventral valve from the area forward to the anterior margins of the visceral cavity. The visceral area of the dorsal valve is narrow, elongate, and extends forward to the anterior third of the valve.

Owing to the small size of the shell and the exfoliation along the margins, no one valve shows all of the muscle scars belonging to it. In Plate XLIX, figure 1a, the outside lateral, middle lateral, and central scars are beautifully defined, but the transmedian and anterior laterals have not been observed in the ventral valve. Many specimens show the anterior laterals and centrals of the dorsal valve, also the transmedian. The outside and middle laterals appear to be combined in one scar a little anterior to the transmedian. The umbonal and pedicle scars have not been observed.

Of the markings left on the shell by the vascular system the main or trunk canals are the most prominent. They are, however, rather indistinct in most examples of the dorsal valve and not specially prominent in the ventral valve. The channels occupied by the fine branches of the exterior lateral canals are well shown by Plate XLIX, figures 1a and 1c.

Observations.—I have made a very close examination of Matthew's type material, which he kindly sent to me for examination, but do not find the muscle scars of the ventral valve as shown in his figure 1g [Matthew, 1903, Pl. XVI]. On the contrary, as shown in my Plate XLIX, figure 1a, the outside and middle laterals and central muscle scars are arranged very much as in *Obolus*. It is exceedingly difficult to determine the exact position and size of the muscle scars, but with a strong magnifying glass and reflected light the dull surface of the point of attachment can often be determined. The peculiar arrangement of the muscle scars indicated in Matthew's figure [1903, Pl. XVI, fig. 1g] results from examining the specimen in a light which raises the ridges bounding the muscle scars so as to give the effect of transverse lines. I find that the scars are not placed in exactly the same position on the two sides, and that on the left side it is practically impossible to determine the outside laterals. In the study of such minute objects there will always be an opportunity for different interpretation, but with the experience I have had in the study of the Cambrian Brachiopoda, I think the position given the muscle scars in figure 1a is essentially correct. The characteristic transverse sculpture refers the species to *Westonia*. It is a beautiful shell and one of the most striking forms of this type from the Cambrian rocks.

The specific name is derived from "Escasonie," a local name for that part of Cape Breton in which the species occurs.

FORMATION AND LOCALITY.—Upper Cambrian: (325 [Matthew, 1903, p. 208]) Arenaceous shales possibly from the horizon of the *Peltura fauna* (Division C3b), on McAdam shore; and (10r)^a arenaceous shales of Division C3a? of Matthew at McAdam shore; both on East Bay, east of Bras d'Or Lake, southeastern Cape Breton, Nova Scotia.

Middle? Cambrian: (10o)^a Arenaceous shales in the railroad cut on the shore of Bras d'Or Lake, at Barachois; and (11z) sandstone on Big Ridge, 2 miles (3.2 km.) south of Marion Bridge, on the canal of John McDougald; both in southeastern Cape Breton, Nova Scotia.

OBOLUS (WESTONIA) EUGLYPHUS (Walcott).

Plate XLVIII, figures 1, 1a-f.

Obolus (Lingulella) euglyphus WALCOTT, 1898, Proc. U. S. Nat. Mus., vol. 21, pp. 402-403. (Described and discussed essentially as below as a new species.)

Obolus (Westonia) euglyphus WALCOTT, 1901, Proc. U. S. Nat. Mus., vol. 23, p. 691. (Merely changes generic reference.)

General form ovate, with the ventral valve subacuminate, and the dorsal valve broad ovate in outline. There is some range of variation in the outline of the valves; this may be seen by comparing figures 1, 1b, and 1c of Plate XLVIII. The convexity of the valves is fairly strong and is nearly the same in each. A ventral valve 11 mm. in length has a width of 8 mm., convexity 1.5 mm.; and a dorsal valve 9 mm. in length has a width of 8 mm., convexity 1.5 mm.

The outer surface of the shell is marked by strong concentric lines and striæ of growth and a complex system of lamellose striæ of the type of those on *Obolus (Westonia) ella* (Hall and Whitfield). The striæ have a transverse direction, are irregular, and sometimes inosculate. They are somewhat coarser than those on the surface of *O. (W.) ella* (Pl. XLVII, fig. 11) and finer than those of *O. (W.) aurora* (Hall) (Pl. XLVI, figs. 1h and 1g). They are also less irregular than those of *O. (W.) ella*, and more so than those of *O. (W.) aurora*, the result being a surface character intermediate between those of the species mentioned. When the outer layer is exfoliated the surface of the inner layer is marked by numerous fine, radiating striæ (Pl. XLVIII, fig. 1b) and concentric lines of growth. The cast of the inner surface of the shell shows rather numerous papillæ that fill the pits or punctæ in the shell. The shell is strong and formed of a thin outer layer and several inner layers or lamellæ that are arranged very much as in *Lingulella acutangula* (Roemer) (Pl. XVII).

As shown by casts of the interior the cardinal area of the ventral valve is rather long and well extended out on the cardinal slopes. It is divided at the center by a cast of a strong, rather deep pedicle furrow, and about three-fifths of the distance between the pedicle furrow and the lateral margin by a sharp, narrow flexure line. The striæ of growth cross the area parallel to its base. Only a few traces of them are preserved in the pedicle furrow. The area formed a thin shelf between the pedicle groove and the lateral margins, the undercut extending far back under the area as in *L. acutangula*. This is shown in the cast by a thin projection of the embedding rock over the area (Pl. XLVIII, figs. 1c and 1d). The area of the dorsal valve is lower and less prominent. It arches forward at the median line and extends well out on the cardinal slopes.

The cast of the visceral cavity (v) of the ventral valve includes the heart-shaped pit (x) and a slight trace of the trapezoidal area, in which the central muscle scars and the middle and outside lateral muscle scars occur. There are no traces of a median septum in the ventral valve, and it is only slightly indicated in one specimen of the dorsal valve. This is owing, however, more to the condition of preservation of the specimen than to the character of the septum. No muscle scars are clearly defined in either valve. Of the vascular system the main or trunk sinuses are fairly well shown in the ventral valve (Pl. XLVIII, figs. 1c and 1d), but less so for the dorsal valve (Pl. XLVIII, fig. 1e).

Observations.—This form has the general shape of *Lingulella acutangula* (Roemer), but differs in being more ovate; it also differs in the arrangement of the markings on the interior

^a The specimens from Localities 10o and 10r are somewhat doubtfully referred to this species.

of the valves, particularly the dorsal. In *Obolus* (*Westonia*) *euglyphus* the traces remaining on the casts indicate a close resemblance to *O.* (*W.*) *ehuarensis* (Walcott), and the surface ornamentation is of the same character. Attention has been called to the character of the surface, which is intermediate between that of *O.* (*W.*) *ella* (Hall and Whitfield) (p. 456) and *O.* (*W.*) *aurora* (Hall) (Pl. XLVI).

This species differs from *Lingulella lineolata* (Walcott) in its surface characters, thickness of shell, and usually in outline; it is also usually a larger species, although a few examples of *L. lineolata* approach it in size. From *O.* (*W.*) *ehuarensis* it differs in being much more elongate and proportionately more ovate in outline.

FORMATION AND LOCALITY.—Middle Cambrian: (74c) "Tonto" sandstone, at the head of Lava Canyon; and (74) sandstones about 300 feet (91.4 m.) above the base of the Tonto group, at the head of Nunkowcap Valley; both in the Grand Canyon of the Colorado, Arizona.

OBOLUS (WESTONIA) FINLANDENSIS Walcott.

Plate XLVIII, figures 3, 3a-b.

Obolus (*Westonia*) *finlandensis* WALCOTT, 1902, Proc. U. S. Nat. Mus., vol. 25, pp. 611-612. (Described and discussed as below as a new species.)

General form elongate ovate, with the ventral valve subacuminate and the dorsal valve ovate in outline. Convexity of the two valves moderate. A ventral valve 11 mm. in length has a convexity of about 1.25 mm., and a dorsal valve 8 mm. in length has a convexity of 1 mm. above the plane of the margin.

The outer surface of the shell is marked by concentric lines of growth with very fine interstitial striæ. The latter are crossed by fine, radiating striæ that are interrupted more or less by the concentric lines of growth. In addition to the concentric and radiating striæ there is a series of imbricating lines that are slightly oblique to the longitudinal axis of the shell. These lines terminate at right angles to the margins, curving inward and backward apparently to the opposite side. This type of ornamentation is much like that of several species of *Westonia*, except that it is somewhat more complicated.

The cast of the interior of the shell shows the interior surface to have been marked by scattered punctæ that had a tendency to gather concentrically on the lines of growth. A few rather strong radiating striæ also occur outside of the visceral area.

The shell is rather thick. It is formed of a thin outer layer and several inner layers or lamellæ that are more or less oblique to the outer surface and marked near the front margin by fine radiating striæ. The largest specimen has a length of 11 mm., with a width of 7 mm. A dorsal valve of the same width has a length of 8 mm.

The area of the ventral valve is unknown. That of the dorsal valve is strongly defined and extends well forward on the cardinal slopes. It is marked by transverse striæ of growth parallel to the base.

The only interior markings known are in the dorsal valve. These indicate the course of the main vascular sinus, and the size and length of the median ridge, also the position of the central muscle scars.
